Abstract

BRAF mutant colorectal cancers (CRC) mostly arise via an alternate pathway distinguished from the classical adenoma-carcinoma sequence involving *APC* and *KRAS* mutations. *BRAF*-driven tumors have an increased incidence of promoter CpG island methylator phenotype (CIMP)-high, microsatellite instable (MSI) phenotype, lack of concurrent mutations of *APC*, mucinous histology, and location on the right side of the colon. Although these characteristics are constantly observed in *BRAF* mutant CRCs, how this *BRAF* mutation induces this type of tumor is not clear.

To understand this, we modeled the early carcinogenesis of colorectal cancer by inducing *BRAF*^{V600E} and *KRAS*^{G12D} individually in organoids prepared from mouse proximal colon and subsequently determined the genome-wide gene expression, DNA methylation, and genetic changes in combination with growth properties and induction of tumor formation.

The *BRAF*^{V600E}, but not *KRAS*^{G12D}, mutations induced various features of progressive transformation consisting of increased spheroid formation of the organoids with internal dysplastic polypoid growth. *BRAF*^{V600E} organoids acquired an ability to grow without stem cell niche factors such as Wnt3a, R-Spondin and Noggin. These above phenotypic changes are phenocopies of *APC* mutations in organoids wherein the Wnt pathway is activated. Indeed, *BRAF*^{V600E} drives sustained up-regulation of Wnt targets and stem cell genes and suppression of differentiation genes regardless of whether niche factors are added. Furthermore, in some of the transformed organoids, sequencing revealed

mutations in b-catenin. Finally, and most excitingly, induction of *BRAF^{V600E}*, but not *KRAS^{G12D}*, induced complete transformation forming xenograft tumors in immunodeficient mice. The tumors exhibit histological characteristics of mucinous adenocarcinoma, which is highly associated with the *BRAF^{V600E}* mutation in human CRCs. In addition, analyses of genome-wide methylation revealed increased DNA methylation in CpG island promoters of many genes including Wnt negative regulators such as *Sfrp1*, *Sfrp2*, *Wt1* and *Sox17* and CIMP genes including *p16* and *Igfbp7* in the *BRAF^{V600E}* mutant organoids.

In conclusion, mouse colon organoids expressing *BRAF^{V600E}* recapitulate features of the human right-sided CRC phenotype with adoption of a stem cell niche factor independency, activation of the Wnt pathway, induction of CpG island methylation in Wnt negative regulators and CIMP panel genes, and activating Wnt-pathway mutations.

Preface

All the work presented in this dissertation is based on the experiments and analysis conducted in Baylin/Easwaran laboratory at the Sidney Kimmel Comprehensive Cancer Center of Johns Hopkins University School of Medicine or in collaboration with other core laboratories in Johns Hopkins University.

The project originally consisted of three parts: in vitro, ex vivo and in vivo modeling of colorectal cancer (CRC) by engineering mouse colon organoids with *BRAF*^{V600E} or *KRAS*^{G12D} mutations. This above ex vivo modeling is thus revealed to be an excellent system to study early events of tumorigenesis for CRC. I successfully induced mutations, *BRAF*^{V600E} and *KRAS*^{G12D} separately, in colon organoids and analyzed their phenotypes and molecular changes including gene expression and DNA methylation. Most of the work presented in this dissertation is based on the physiological and pathological phenotyping and molecular characterization of the mutant organoids.

Although most of the techniques used here pertain to growth of organoids, our phenotyping and molecular analyses of these were adopted from previously published articles and shared information from our collaborators, I modified their techniques to meet the objectives of this project. I hope the methods described here are also useful for other research projects in the future.

Acknowledgement

First and foremost, I would like to thank my co-mentors, Dr. Stephen Baylin and Dr. Harihran Easwaran, for their endless support and guidance during my thesis work. Their advice, support and guidance have been the most crucial components of this thesis project from its inception to completion. I cannot imagine how I would be able to finish this project without them. The regular discussions we had were very helpful and encouraging. I felt very fortunate to get trained under their mentorship.

I also would like to thank my thesis committee: Dr. Ben Ho Park, Dr. Srinivasan Yegnasubramanian and Dr. Nicholas C. Zachos for all their advice and help with the project. As a committee chair, Dr. Ben Ho Park gave me great advices keeping me on the right track. I really appreciate his advices on the thesis work and future career in general. I also appreciate Dr. Srinivasan Yegnasubramanian's help with methylation analysis and other great advices throughout the thesis work. It has been tremendous help for me to accomplish this thesis. I also need to thank Dr. Nicholas C. Zachos for his collaboration in establishment of organoid culture. Without his help and collaboration, I would not be able to learn and establish organoid culture for my thesis work.

I need to thank Dr. Julie In. I learned the organiod culture technique from Dr. Julie In. Without her help, it would be impossible for me to learn the technique in a very short time and establish organoid culture in our lab. I also want to thank Dr. Elana Fertig for her help with gene expression pattern analysis. It was a great opportunity to learn bioinformatics tools and statistical ideas behind it. I also need to thank Dr. Shinji Maegawa and Dr. Tao Yong for their

help with targeted methylation analysis. I really feel fortunate to have Dr. Julie, Dr. Elana Fertig, Dr. Shinji Maegawa and Dr. Tao Yong as collaborators and colleagues.

I also would like to thank members of Dr. Stephen Baylin and Dr. Hariharan Easwaran lab and tumor biology program. Especially, I would like to thank the faculty members in our group, Dr. Barry Nelkin, Dr. Cynthis Zahnow, Dr. Nita Ahuja, Dr. Douglas Ball, Dr. Robert Casero, Dr. James Herman and Dr. Malcolm Brock, for great advices and discussions. I am also very thankful to Kathy Bender, Tammy Means and JoAnn Murphy for their administrative helps and Ray-whay, Tina Largent and Lauren Murphy for their help with tissue culture, experiments and material procurement. In addition, I also want to thank Dr. Yi Cai, Dr. Wenbing Xie, Dr. Michelle Vaz, Dr. Kate Chiappinelli, Dr. Christina Destefano, Michael Topper, Dr. Benjamin Leadem, Dr. Heather O'Hagan, Dr. Hsing-Chen Tsai, Dr. Jianjun Luo, Dr. Lorraine Pelosof, Dr. Khadijah Mitchell, Dr. Weijie Poh, Dr. Yang Zhang and Dr. Andre Kydd for the helpful discussions and advices.

I also like to mention the Pathobiology graduate program for providing me the opportunity to pursue my PhD degree at Johns Hopkins. Especially, I would like to thank Mrs. Margaret Lee and Mr. Al Njoo for providing me and other Margaret Lee fellows funding for the first year. The fellowship provided us a great opportunity to start our scientific career in such a great scientific community, Johns Hopkins Univeristy. In addition, I want to thank former and present director, Dr. Noel Rose and Dr. Lee Martin, and program faculty members for providing me great advices throughout the PhD training and former and present

program administrative staffs, Wilhelmena Braswell, Nancy Nath, Stacey Morgan and Tracie McElroy for all the administrative helps during my PhD training. I also need to thank program colleagues and classmates for help during the course work and thesis work.

Finally, I would like to thank my family and friends for their limitless support and encouragement throughout my PhD training. Especially, I would like to thank my grandfathers from maternal and paternal sides. They had been always supportive and encouraging me to pursue my dreams. In addition, I also want to thank Stella Suyong Lee for being supportive and helpful during my entire PhD training.

Chapter 1. Introduction

1.1 Cancer genetics and epigenetics

Cancer is a result of abnormal regulation of normal processes such as proliferation, cellular death, genome maintenance, angiogenesis, cellular metabolism and immune surveillance (Hanahan and Weinberg, 2011). The abnormal regulation of these processes gives the cancerous cells a selective advantage over normal cells in growth, survival and evasion from immune surveillance and allows for malignant progression. All of these abnormalities are direct or indirect results of genetic and epigenetic changes that cause loss of function for tumor suppressor genes(TSGs) and genome surveillance genes and activation of oncogenes(OCGs).

Genetic alterations are common causes of loss of function for TSGs and activation of oncogenes. Genetic alterations causing activation of oncogenes include gene amplification, activating missense point mutations, and translocation which causes formation of fusion proteins that induce inappropriate gene activation. In contrast, inactivating missense or nonsense point mutations and deletions of chromosome regions are common genetic alterations that cause loss of TSGs such as genome surveillance genes, cell cycle checkpoints and cell death related genes. In recent sequencing studies of 3284 tumors, a total 125 driver mutations were discovered based on mutation frequencies (Vogelstein et al., 2013). Genes with the driver mutations are

CHAPTER 1. INTRODUCTION

involved in 12 pathways that regulate three core cellular processes including cell fate, cell survival and genome maintenance (Vogelstein et al., 2013).

Another important way of losing TSGs function and activation of oncogenes is epigenetic alteration in the cancer genome. Although genetic alterations have traditionally been viewed as the main driver of cancer development, recently the paradigm has now been expanded to incorporate the disruption of epigenetic regulatory mechanisms (Baylin and Bestor, 2002; Baylin and Jones, 2011; Baylin and Ohm, 2006; You and Jones, 2012). Gene silencing of TSGs through promoter hypermethylation is a common form of epigenetic disruption in cancer (Baylin and Jones, 2011). For instance, genes controlling the cell cycle and DNA repair, such as RB, BRCA1/2, and PTEN, are known to have abnormal promoter region DNA methylation and associated abnormal gene silencing as well as undergoing mutations and deletions in cancer (Hatzia Apostolou and Iliopoulos, 2011). In addition, histone modification and nucleosome remodeling are other important epigenetic regulations that can be disrupted in cancer. Histone modifications at specific amino acid residues in gene regulatory regions can normally help control gene activation or repression. For instance, trimethylated H3 at lysine 4 is enriched in active gene promoters. In contrast, Trimethylated H3 at lysine 27 or trimethylation H3 at lysine 9 are enriched in inactive promoters (Arnold et al., 2016; Baylin and Jones, 2011; Hatzia Apostolou and Iliopoulos, 2011). These modifications are regulated by histone acetyltransferases, deacetylases methyltransferases and demethylases. Nucleosome remodeling is another key mechanism for regulation of gene

expression. As more and more mutations are discovered in the nucleosome remodeling proteins in cancers, the importance of their role in tumorigenesis is increasing (Bhattacharjee et al., 2016; Biegel et al., 2014; Geng et al., 2016; He et al., 2016; Huang et al., 2015; Kadoch and Crabtree, 2015; Levin et al., 2015; Malonia et al., 2014; Mayes et al., 2014; Nio et al., 2015; Oike et al., 2013; Pfister et al., 2015; Soshnikova et al., 2016; Wang et al., 2016; Wu et al., 2016a; Wu et al., 2016b; Wu et al., 2014; Xu et al., 2015; Zhang et al., 2016a; Zhang et al., 2016b; Zollner et al., 2015). However, the direct role in tumorigenesis is still unknown.

1.2 Specific genetics and epigenetics of colorectal cancer

It is estimated that 1.3 million persons in the world will be found to have colorectal cancer (CRC) in 2012. CRC is the third most common cancer in men and the second most in women (Arnold et al., 2016). It is also one of the most well studied cancers in terms of clinical, pathological and molecular characteristics. Although, in many instances, it is regarded as a single entity, CRCs are quite heterogeneous. There have been many efforts to separate CRCs into different types based on molecular or morphological features. For genetic changes, driver mutation status such as *KRAS*, *BRAF*, and *APC*, chromosomal instability and frequent mutations for repeat sequences (microsatellite instability) have been frequently used. For epigenetic changes, a phenotype wherein many genes undergo abnormal promote CpG island methylation known as the CpG island Methylator Phenotype (CIMP) has been appreciated since the studies of Minoru Toyota and colleagues (Toyota et al., 1999). These above genetic and

CHAPTER 1. INTRODUCTION

epigenetic features allow us to divide CRCs into the following 5 groups although the distinction is not always clear-cut due to the presence of some CRCs with mixed features, (Jass, 2007):

Group 1 (12%)- CIMP-high, *MLH1* methylation, Microsatellite instability (MSI)-high. Chromosomal instability (CIN)-negative and frequent *BRAF* mutations.

Group 2 (8%)- CIMP-high, partial *MLH1* methylation, Microsatellite stable or MSI-low, CIN-negative and *BRAF* mutations.

Group 3 (20%)- CIMP-low, *MGMT* methylation, MSS or MSI-low, CIN positive, and *KRAS* mutation.

Group 4 (57%)- CIMP-negative, MSS, CIN, *APC* and *KRAS* mutation.

Group 5 (3%)- CIMP-negative, MSI-H, CIN-negative and mutations in DNA mismatch repair genes (can occur as a genetic disorder in families termed the Lynch syndrome) and *APC* mutations.

Group 1 and 2 CRC tumors share the same precursor lesions, morphological features and anatomic location: serrated polyps, mucinous morphology, and occurrence on the right side of the colon. Group 5 tumors also occur predominantly on the right side but have adenoma as a precursor lesions and are rarely mucinous. Group 3 tumors have either serrated polyps or adenomas as precursor lesions and mostly occur on left side. Group 4 predominantly develop from adenoma on left side and are rarely mucinous (Figure 1.1).

CHAPTER 1. INTRODUCTION

As the most prevalent tumor type in colon, group 4 tumors were subjected to early sequencing efforts by Bert Vogelstein and colleagues and their studies documented sequential accumulation of mutations such as *APC*, *RAS*, *PI3K* and *TGF- β* in a paradigm commonly known as the Vogelgram (Jones et al., 2008). Group 1, 2 and 3 CRC, which are the main object of this thesis, were classified in later studies, and their origins in serrated precursor lesions were proposed (Bettington et al., 2013; Burnett-Hartman et al., 2013; Ensari et al., 2010; Inoue et al., 2015; Kambara et al., 2004; Kriegl et al., 2011; Li and Burgart, 2007; Makinen, 2007; Michalopoulos and Tzathas, 2013; Minoo et al., 2007; Mohammadi et al., 2013; Murakami et al., 2015; O'Brien et al., 2006; Sakai et al., 2016; Snover, 2011; Spring et al., 2006; Vakiani and Yantiss, 2009; Yang et al., 2004). Although recent studies with early serrated lesions discovered that *BRAF* mutation precedes accumulation of DNA methylation in group 1 and 2 (Hinoue et al., 2009), the exact sequential changes remain to be elucidated.

Among CRC subtypes, groups 1 and 5 have the best prognosis (Bettington et al., 2013; Ensari et al., 2010; Kriegl et al., 2011; Li and Burgart, 2007; Snover, 2011; Spring et al., 2006). In turn, this correlates with having a high MSI status and high number of infiltrating lymphocytes (Pai et al., 2012). It is suggested that MSI causes high mutation burden and the mutations themselves or neo-antigens from the mutated genes induce the immune reaction and cause infiltration of lymphocytes (Bettington et al., 2013; Ensari et al., 2010; Kriegl et al., 2011; Li and Burgart, 2007; Snover, 2011; Spring et al., 2006). It has also been recently shown that this mutational burden and lymphocyte infiltration scenario correlates with

CHAPTER 1. INTRODUCTION

better response to immune checkpoint blockade with Pembrolizumab (Anti-PD-1) (Le et al., 2015). In contrast, group2 tumors seem to have the worst prognosis. They tend to have less lymphocyte infiltration and poor differentiation and be more invasive (Bettington et al., 2013; Ensari et al., 2010; Kriegl et al., 2011; Li and Burgart, 2007; Snover, 2011; Spring et al., 2006).

1.3 Stem cell and Wnt in colorectal cancer

In humans the entire intestinal lining epithelium is replaced every 5 to 7 days (Basu et al., 2016). This rapid replacement is fueled by the proliferation of stem cells at the base of crypt and subsequent differentiation of progenies of these cells as they migrate upward toward the intestinal lumen where they undergo apoptosis. This cellular turnover enables normal homeostasis of the intestine (Basu et al., 2016). The normal process of proliferation and differentiation of intestinal stem cells is governed by a gradient of Wnt signaling (Basu et al., 2016) which is the strongest at the crypt base and gradually decreases toward the luminal side. The strong Wnt signaling supports stem cell maintenance and proliferation at the crypt base and the decreasing Wnt signaling along the crypt supports epithelial differentiation of stem cells (Basu et al., 2016).

Cancer stem cells in colorectal cancers are suggested to have a similar role as intestinal stem cells in giving rise to progenitors that populate the majority of the tumor cells. Two models have been proposed to describe the origin of cancer stem cells in CRCs: the top-down and the bottom up model (Basu et al., 2016). The top-down model suggests that differentiated epithelial cells re-acquire stem

CHAPTER 1. INTRODUCTION

cell-like properties through hyperactivation of Wnt signaling and form aberrant crypt foci. On the other hand, the bottom-up model proposes that stem cells at the crypt base acquire ability to migrate upward without normal differentiation through Wnt hyperactivation. Although the suggested origin of cancer is different, both models require Wnt activation in either differentiated cells or stem cells. The importance of Wnt signaling in CRC tumorigenesis was recently demonstrated by formation of tumors by loss of *APC* and regression of tumors by restoration of *APC* even with retention of other oncogenic mutations such as *KRAS* and *p53* (Basu et al., 2016; Dow et al., 2015; Guerrero-Preston et al., 2014; Jorissen et al., 2015; Matano et al., 2015; Pronobis et al., 2015; Strum, 2016; Zachos et al., 2016). Also, in model systems, Wnt suppression by expression of a Wnt antagonist protein HoxA5 in colon cancer cells also suppresses tumor growth and metastatic progression (Ordonez-Moran et al., 2015).

In CRCs, Wnt pathway activation can occur through genetic and epigenetic alterations in various components of the Wnt regulatory pathway (Basu et al., 2016; Dow et al., 2015; Guerrero-Preston et al., 2014; Jorissen et al., 2015; Matano et al., 2015; Pronobis et al., 2015; Strum, 2016; Zachos et al., 2016). Germline mutations of *APC* cause familial adenomatous polyposis and approximately 70-80% of sporadic CRCs also harbor *APC* mutations or deletions. *APC* is a major binding partner and regulator of the canonical Wnt signaling pathway. In the absence of Wnt ligand, *APC* forms a destruction complex with the scaffold protein Axin to promote subsequent phosphorylation of β -catenin by Casein kinase1 (CK1) and Glycogen synthase kinase 3 β (GSK3 β) (Fearon, 2011).

CHAPTER 1. INTRODUCTION

The phosphorylation of b-catenin leads to its degradation by the ubiquitin proteasome pathway. In the presence of Wnt ligand, the destruction complex disintegrates when there is recruitment of Axin protein and GSK3b to a cognate Wnt receptor complex consisting of the Frizzled and lipoprotein receptor-related protein (Fearon, 2011). The disruption of this destruction complex will lead to accumulation of b-catenin in the cytoplasm and its localization to the nucleus where it activates Wnt target gene expression along with co-activators such as CBP/p300 (Figure 1.2). In the case of *APC* mutations or deletion, the b-catenin is accumulated regardless of the presence of Wnt ligand due to failure of proper formation of the destruction complex. Mutations in other components of Wnt pathway including Axin, b-catenin and TCF4 are also reported in CRCs. However, their functional role in tumorigenesis remains to be elucidated (Fearon, 2011).

An epigenetic change such as the abnormal promoter region DNA methylation, discussed earlier, can also play important role in activation of Wnt in CRCs. Occasionally, this occurs for *APC* (Arnold et al., 2004; Coyle et al., 2007; Erdem et al., 2014; Fu et al., 2009; Furlan et al., 2014; Haluskova et al., 2015; Hiltunen et al., 1997; Jin et al., 2001; Juhlin et al., 2010; Segditsas et al., 2008; Sievers et al., 2006; Wang et al., 2009; Zhang et al., 2007; Zhang et al., 2008). Also, extremely frequently in colon polyps and CRCs, such abnormal DNA methylation occurs in the promoter regions of the Wnt antagonists, *SFRP1*, *SFRP2*, *SFRP5*, *DKK2*, *WIF1* and *SOX17* in the transition from normal to colorectal cancers (Murakami et al., 2015; Silva et al., 2014). *SFRP2* and *SOX17* themselves are Wnt target genes which normally can work as a negative feedback

loop for the Wnt pathway (Silva et al., 2014) (Figure 1.2). The suppression of all of these genes through DNA methylation is proposed to disrupt the negative feedback loop and induce hyperactivation of the Wnt pathway. The increase in DNA methylation has been associated with Wnt activity in CRC (Silva et al., 2014).

1.4 Organoids as an *ex vivo* model of gastrointestinal pathology

Model systems have been the centerpiece of biomedical and biological research being used to recapitulate biological and pathological processes. Animal models are the most close recapitulation of human biology and pathology, but these can be limited by having a confounding variability and limited accessibility for imaging and molecular assays. Although 2D monolayer cultures have their advantages and have played a critical role in modern advancement of biomedical and biological research, they often lack proper cell to cell and cell to matrix interactions and hierarchal organization. More importantly, most 2D cultures are either cancer or transformed cell wherein the genome and epigenome have already undergone significant changes. Early 3D culture systems such as cell spheroid cultures also lack the hierarchal organization of stem cell and progenitor cells and thus are unable to have both ongoing self renewal and differentiation processes (Date and Sato, 2015). Thus, although the animal models, 2D cell culture and early 3D cell culture have been very important tools for discovery so far, they don't cover the gap between the cellular level and the organ level.

CHAPTER 1. INTRODUCTION

The recently developed methodology by Clevers and colleagues to use stem cell derived organoids as a model will potentially, and robustly fill the gap. The model, wherein mouse and human cells, best studied to date as below from intestine, closely recapitulates a renewing cell system wherein, crypt stem cells, differentiation of their progeny, and apoptosing cells filling a lumen-like structure are all represented (Sato et al., 2009; Visvader and Clevers, 2016). Organoids recapitulate the hierarchal organization, cell-cell interaction, and cell-matrix interaction and have the capacity for both self-renewal and differentiation. While a wide variety of organoids have been generated including brain, lung, liver and intestine, the intestinal organoid system is one of the most well established and most widely used system currently. Evans et al. (1994) firstly cultured primary adult intestinal crypt in collagen type I –coated tissue culture vessels (Date and Sato, 2015; Evans et al., 1994). However, the culture was good for 1-2 weeks. Later, long lasting culture of neonatal intestinal mucosa mixed with mesenchymal fibroblasts was developed as an air-liquid interface culture in 2009 by Ootani et al (Date and Sato, 2015; Ootani et al., 2009). More recently, a long lasting mini-gut organoid culture was developed for mouse ISCs (Intestinal stem cells), wherein the culture can be derived from a single intestinal stem cell without mesenchymal fibroblasts or other cells (Date and Sato, 2015). The mini-gut organoids culture is maintained in a mesenchymal-free environment comprising Matrigel and intestinal stem cell niche factors such as EGF, Wnt3a, Noggin and R-spondin. This mini-gut organoid recapitulates in vivo intestinal hierarchal organization and normal self-renewal and differentiation: single stem

CHAPTER 1. INTRODUCTION

cells initially form villus-like cystic structures and subsequently the cysts forms crypt-like budding structures. Intestinal stem cells and Paneth cells reside at the tip of the budding structure and differentiating cells migrate toward the central cystic structure recapitulating the normal process of self-renewal and differentiation of intestinal stem cells and epithelial cells.

1.5 Summary of dissertation

In this dissertation, I describe in Chapter 2, mutual exclusivity between *BRAF* mutation and *APC* mutations in CRCs based on my analysis of The Cancer Genome Atlas (TCGA) CRC database and previously published data (Cancer Genome Atlas, 2012; Jorissen et al., 2015). Unlike *KRAS* mutations, *BRAF* mutations have a tendency towards being mutually exclusive with *APC* mutations in CRCs. As discussed earlier, the latter are the main drivers of Wnt activation in CRC. In Chapter 3, I show how *BRAF* mutations, in contrast to *KRAS* mutations, induce stem cell niche factor independent growth and tumorigenic transformation in mouse proximal colon organoids without engineering a concurrent *APC* mutation. This *BRAF* mutation induced single-step transformation starkly contrasts with previous studies showing requirement of multiple genetic hits, including *APC* disruption, for *KRAS* mutation to drive tumorigenesis (Drost et al., 2015). Upon induction, both *BRAF*^{V600E} mutation and *KRAS*^{G12D} mutation promoted sphere formation which is the same phenotype as described in *APC* mutant organoids. Furthermore, only *BRAF*^{V600E} mutant organoids gained independency in growth from having to add stem cell niche

CHAPTER 1. INTRODUCTION

factors such as EGF, Wnt3a, R-spondin and Noggin and tumorigenicity in Xenograft assays without any concurrent *APC* mutations. Molecular analysis revealed *BRAF^{V600E}* mutant organoids autonomously activate Wnt signaling and stem cell signaling without external signaling from stem cell niche factors. Methylation analysis revealed the *BRAF^{V600E}* organoids to have the CpG Island Methylator Phenotype (CIMP) with the genes affected by increased DNA methylation in promoter CpG islands including multiple Wnt negative regulator genes and genes that would normally cause senescence and blunt stem cell activity, and that would normally induce and maintain differentiation. These findings strongly suggest that the abnormal methylation plays an important role in the autonomous activation of Wnt and stem cell signaling pathways. Finally, b-catenin mutations were observed in two of the *BRAF^{V600E}* mutant organoids indicating that *BRAF^{V600E}* activation can lead to selection for genetic changes which foster Wnt-independency and cooperate with the epigenetic alterations.

Figure 1.2

Figure 1.2 Summary of Wnt pathways and the cellular hierarchy and stem cell niche factors in colon crypts and colon organoids

(A) Red shade represents Wnt activation by Wnt ligands. As Wnt ligands bind to their receptor, Frizzled and LRP5/6, their cytosolic domains induce dissociation of β -catenin destruction complexes by sequestering their key components such as DVL, GSK3 β , and AXIN. Therefore, β -catenins are protected from phosphorylation by GSK3 β and subsequent degradation by ubiquitin-proteasome pathway. Eventually, non-phosphorylated β -catenins are translocated to nucleus and activate its target gene expression in corporation with TCF. Purple shade represents a situation where Wnt ligand is not present or the Wnt pathway is negatively regulated by Wnt negative regulators. When Wnt ligands are not present, β -catenin destruction complex sequester β -catenins and subsequently induce their degradation through ubiquitin-protease pathway. The lack of β -catenin in the nucleus let TLE bind to TCF and suppress expression of Wnt target genes. There are several Wnt negative regulators. SFRP inhibits at the level of Wnt ligands through direct binding and sequestration of them. On the other hands, DKK binds to Wnt ligand receptor, LRP5/6 and Frizzled proteins and, therefore, inhibit their interaction with Wnt ligands. WT1 induces expression of WID, which is antagonist of Dvl. Sox17 is an antagonist of TCF though direct binding. (B) Colon crypt is consist of intestinal stem cells (ISC), Paneth cells, +4 cells, and differentiated enterocytes. The self-renewing ISCs reside at the bottom of the crypt and their progenies migrate upward along the crypt. The maintenance of this cellular hierarchy is highly regulated by the stem cell niche

CHAPTER 1. INTRODUCTION

factors such as Wnt3a, RSPO and Noggin and differentiation factors BMP. Colon organoid maintains the same cellular hierarchy. The ISC reside at the tip of budding structures that grow out from the central cystic structure. The differentiating enterocyte migrates toward the central cystic structure.

Chapter 2: Mutual exclusivity between *BRAF* and *APC* mutations in colorectal cancers

2.1 Introduction

APC mutations are regarded as the main driver genetic alterations in CRCs. In fact, these are one of the earliest events in many CRCs and one of the most prevalent mutations in these cancers (Jorissen et al., 2015). The majority of *APC* mutations are frameshift or nonsense mutations, which results in the loss of *APC* function, disruption of the destruction complex for beta catenin leading to accumulation of this protein and Wnt activation (Fearon, 2011). In the tumors with *APC* mutations, aberrant Wnt activation is observed early on at the low-grade adenoma stage and in the majority of the cells. Mouse models with *APC* mutations develop adenomas in the small and large intestine with hyperactivation of Wnt signaling (Fearon, 2011). Germline mutations of the *APC* gene also cause familial adenomatous polyposis (FAP) syndrome in humans which is characterized by increased incidence of polyp formation in the colon and increased predisposition to CRC development.

BRAF^{V600E} also has been considered as a driver mutation in a subtype of CRCs. The tumors with *BRAF*^{V600E} tend to have a sessile serrated polyp as a precursor lesion (Ensari et al., 2010; Kambara et al., 2004; Makinen, 2007; Minoo et al., 2007; Snover, 2011; Vakiani and Yantiss, 2009; Yang et al., 2004), mucinous adenocarcinoma as a histopathological type (Ensari et al., 2010;

CHAPTER 2. MUTUAL EXCLUSIVITY BETWEEN *BRAF* AND *APC* MUTATIONS IN COLORECTAL CANCERS

Kambara et al., 2004; Makinen, 2007; Minoo et al., 2007; Snover, 2011; Vakiani and Yantiss, 2009; Yang et al., 2004) and have the CpG Island Methylator Phenotype (CIMP)-high and microsatellite instability as molecular features (Hinoue et al., 2009; Ogino et al., 2006). Despite having different histopathological and molecular features, *BRAF* mutant tumors also have increasing levels of Wnt activation as do the *APC* mutant tumors (Murakami et al., 2015). However, unlike for the more rapid increase of Wnt activation in *APC* mutant tumors, *BRAF* tumors undergo gradual increase of Wnt activity as they progress from low to high grade. The same gradual increase of Wnt activity is also observed in mouse intestinal tumors driven by *BRAF* mutation (Rad et al., 2013). In addition, the increase of Wnt activity is associated with increase of DNA methylation in promoter regions of Wnt negative regulators such as AXIN2, SFRP1, SFRP2, and SFRP4 but not with loss of APC expression. It is proposed that epigenetic silencing of these Wnt negative regulators could be the main driver of Wnt activation in the *BRAF* mutant tumors rather than *APC* mutations (Lee et al., 2008; Nosho et al., 2008; Suva et al., 2013; Toyota et al., 1999). There are only a few studies formally investigating these above relationships between *APC* and *BRAF* mutations although it is widely accepted that *KRAS* and *APC* mutations co-occur in vast majority of CRCs. In this chapter, I will discuss the relationships between *APC* and *BRAF* mutations and the unique molecular features of *BRAF* mutant tumors based on data from The Cancer Genome Atlas (TCGA) database and an Australian cohort database.

2.2 Results

2.2.1 *APC* and *BRAF* mutations have a tendency to be mutually exclusive in an Australian CRC cohort

A recent study of an Australian CRC patient cohort included the mutation status of 746 colorectal tumors (Jorissen et al., 2015). Using the data, we examined the relationships between major driver mutations including *BRAF*, *KRAS* and *APC* in the above CRCs. Among 746 tumors, 67 have *BRAF* mutations and only 14 of the 67 tumors have *APC* mutations at the same time. The Fisher's exact test revealed a strong tendency toward mutual exclusivity with Odds Ratio (OR) of 0.09782335 and p-value less than $2.2e-16$ (Figure 2.1A) (Gao et al., 2013). Among the same cohort, 262 tumors harbor *KRAS* mutations and 211 out of 262 tumors have concurrent *APC* mutations. Fisher's test showed a tendency toward co-occurrence with OR of 2.556757 and p-value of $1.096e-07$ (Gao et al., 2013).

2.2.2. *APC* and *BRAF* mutations also have a tendency to be mutually exclusive in the TCGA CRC cohort

Mutational status of *APC*, *KRAS* and *BRAF*, CIMP status, microsatellite instability(MSI) status, hypermutator phenotype, anatomic location and histopathological type of CRCs in the TCGA cohort were retrieved from the TCGA data(Table 2.1) (Cancer Genome Atlas, 2012). As previously reported (Guinney et al., 2015; Hinoue et al., 2009; Hughes et al., 2012; Jass, 2007; Lee et al., 2008; Li

and Lai, 2009; Makinen, 2007; Morkel et al., 2015; Nosho et al., 2008; O'Brien et al., 2006; Ogino et al., 2006; Treanor and Quirke, 2007; Vakiani and Yantiss, 2009; Weisenberger et al., 2006; Yamamoto et al., 2012), *BRAF* mutant tumors are associated with CIMP-H and MSI-H and *KRAS* tumors with CIMP-L and MSS (Figure 2.2) consistent with data from other cohorts.

Among 224 tumors, 21 have *BRAF* mutations and only 8 of the 21 tumors have *APC* mutations at the same time. The Fisher's exact test revealed some tendency toward mutual exclusivity with OR of 0.1388884 and p-value less than 4.25e-05 (Figure 2.3A) (Gao et al., 2013). Among the same cohort, 94 tumors harbor *KRAS* mutations and 80 out of 94 tumors have concurrent *APC* mutations. Fisher's test showed a tendency toward co-occurrence with OR of 2.181095 and p-value of 2.3e-02 (Gao et al., 2013).

In addition, *BRAF* mutant tumors in this cohort tend to have less homozygous *APC* loss (2 out of 8 tumors), which accounts for more than half of the *APC* mutations in *KRAS* mutant tumors (40 out of 77 tumors) and tumors without mutations in *BRAF* and *KRAS* (51 out of 85 tumors) (Table 2.1 and Figure 2.4). Pearson Chi square test revealed that *BRAF* mutant tumors positively associate with wild type *APC* and negatively associate with homozygous *APC* loss.

2.3 Discussion

As discussed in chapter one, among CRC, there are different disease entities rather than one (Guinney et al., 2015; Hughes et al., 2012; Jass, 2007; Lee

et al., 2008; Li and Lai, 2009; Makinen, 2007; Morkel et al., 2015; Nosho et al., 2008; O'Brien et al., 2006; Ogino et al., 2006; Treanor and Quirke, 2007; Vakiani and Yantiss, 2009; Weisenberger et al., 2006; Yamamoto et al., 2012). Among those groups, Group 1 and 2 have a tendency to have mutations in *BRAF* not in *APC* (Figure 1.1). It has been proposed that in these latter tumors epigenetic modulation of the Wnt pathway replaces the role of *APC* mutations. However, the exact process has not been modeled and yet proven. Even the relationships between *BRAF* mutations and *APC* mutations has not been well studied. In this chapter, the association studies with the Australian and TCGA CRC cohorts revealed a negative correlation between *BRAF* and *APC*. Although there is difference in the strength of tendency and significance, both cohorts suggest a mutual exclusivity implicating *BRAF* mutations may not require concurrent *APC* mutations to initiate and drive progression of CRCs in contrast to CRCs with *KRAS* mutations, which appear to require Wnt-activation by *APC* mutations for progression. How *BRAF* mutations drive tumorigenesis without a preceding requirement for Wnt-activation by *APC* mutations will be discussed in detail in Chapter 3 with new evidence discovered through modeling of the *BRAF* mutant CRCs in organoid culture.

2.4 Material and Methods

2.4.1 Analysis of TCGA CRCs

Mutation, CIMP phenotype, MSI status, MLH1 methylation, hypermutator phenotype, anatomic location, histopathologic type and patient's gender were acquired from supplementary data from a previously published article (Cancer Genome Atlas, 2012). The associations were evaluated by Fisher's exact test or Chi square test.

2.4.2 Analysis of Australian CRCs

The mutational information of CRC in the Australian cohort was acquired from a previously reported article (Jorissen et al., 2015). The associations were evaluated by Fisher's exact test or Chi square test.

Table 2.1 Summary of TCGA CRC data for *APC*, *BRAF* and *KRAS* mutations, CpG Island Methylator Phenotype, Microsatellite Instability, anatomic location and histopathology type

Blue color represents APC mutation status. Darkest blue means deletion, lighter blue for frame shift, non-sense or point mutation. Orange and brown stand for *BRAF* and *KRAS* mutations respectively. (Me : methylation, HM: hypermutator, nHM: non-hypermutator, Rt: right, Lf: left, ADC: adenocarcinoma, Muc: mucinous adenocarcinoma, M: male, F: female)

Figure 2.1

A : Australian cohort of 746 cases

| | <i>APC</i> Mutant | Wild type <i>APC</i> |
|-----------------------|-------------------|----------------------|
| <i>BRAF</i> mutant | 14 | 53 |
| Wild type <i>BRAF</i> | 496 | 183 |

* Fisher's exact test

$p < 2.2e-16$, Odd Ratio=0.09782335

*Strong tendency toward mutual exclusivity

B : Australian cohort of 746 cases

| | <i>APC</i> Mutant | Wild type <i>APC</i> |
|-----------------------|-------------------|----------------------|
| <i>KRAS</i> mutant | 211 | 51 |
| Wild type <i>KRAS</i> | 299 | 185 |

* Fisher's exact test

$p=1.096e-07$, Odd Ratio=2.556757

*Tendency toward co-occurrence

C

Odd Ratio Interpretation

| | |
|-----------|---|
| 0 - 0.1 | Strong tendency toward mutual exclusivity |
| 0.1 - 0.5 | Some tendency towards mutual exclusivity |
| 0.5 - 2 | No association |
| 2 - 10 | Tendency toward co-occurrence |
| >10 | Strong tendency toward mutual exclusivity |

Figure 2.1 *BRAF* and *APC* mutations in 746 CRCs in the Australian cohort have a strong tendency toward mutual exclusivity

(A) Fisher's exact test for an exclusivity / co-occurrence between *BRAF* and *APC*. p-value is lower than 2.2×10^{-16} and odds ratio is 0.09782335. Based on cBioPortal's odds ratio interpretation, there is a strong tendency toward mutual exclusivity between *BRAF* and *APC* mutations in this cohort. (B) Fisher's exact test for an exclusivity / co-occurrence between *KRAS* and *APC*. p-value is 1.096×10^{-7} and odds ratio is 2.556757. Based on cBioPortal's odds ratio interpretation, there is a tendency toward co-occurrence between *KRAS* and *APC* mutations in this cohort. (C) Interpretation criteria for odds ratio in cBioPortal (Gao et al., 2013).

Figure 2.2

Figure 2.2 Molecular features of 224 CRC in the TCGA cohort correlate with previous reports on these cancers

(A) Mosaic plot and Pearson Chi square for molecular features such as *BRAF* mutation, CpG Island Methylator Phenotype(CIMP) status and Microsatellite Instability(MSI). As previously reported *BRAF* mutant tumors have a strong association with CIMP-H and MSI-H phenotype and *KRAS* mutant tumors are associated with CIMP-L and MSS phenotype indicating the cohort represents a good spectrum for CRC samples collected.

Figure 2.3

A : TCGA cohort of 224 cases

| | <i>APC</i> Mutant | Wild type <i>APC</i> |
|-----------------------|-------------------|----------------------|
| <i>BRAF</i> mutant | 8 | 13 |
| Wild type <i>BRAF</i> | 166 | 37 |

* Fisher's exact test

p= 4.25e-05, Odd Ratio=0.1388884

*Some tendency toward mutual exclusivity

B : TCGA cohort of 224 cases

| | <i>APC</i> Mutant | Wild type <i>APC</i> |
|-----------------------|-------------------|----------------------|
| <i>KRAS</i> mutant | 80 | 14 |
| Wild type <i>KRAS</i> | 94 | 36 |

* Fisher's exact test

p=2.3e-02, Odd Ratio=2.181095

*Tendency toward co-occurrence

C

Odd Ratio Interpretation

| | |
|-----------|---|
| 0 - 0.1 | Strong tendency toward mutual exclusivity |
| 0.1 - 0.5 | Some tendency towards mutual exclusivity |
| 0.5 - 2 | No association |
| 2 - 10 | Tendency toward co-occurrence |
| >10 | Strong tendency toward mutual exclusivity |

Figure 2.3 *BRAF* and *APC* mutations in 224 TCGA CRCs cohorts have some tendency toward mutual exclusivity

(A) Fisher's exact test for an exclusivity / co-occurrence between *BRAF* and *APC* mutations. p-value is $4.25e-05$ and odds ratio is 0.1388884 . Based on cBioPortal's odds ratio interpretation, there is some tendency toward mutual exclusivity between *BRAF* and *APC* mutations in this cohort. (B) Fisher's exact test for an exclusivity / co-occurrence between *KRAS* and *APC* mutations. p-value is $2.393e-02$ and odds ratio is 2.181095 . Based on cBioPortal's odds ratio interpretation, there is a tendency toward co-occurrence between *KRAS* and *APC* mutations in this cohort. (C) Interpretation criteria for odds ratio in cBioPortal (Gao et al., 2013).

Figure 2.4

Figure 2.4 *BRAF* mutant CRC in the TCGA cohort are positively associated with wild type *APC* and negatively with homozygous *APC* loss.

(A) Mosaic plot and Pearson Chi square test result. *BRAF* mutant tumors are positively associated with wild type *APC* and negatively with homozygous *APC* loss. In contrast, *KRAS* mutant tumor and tumors without mutations in *KRAS* and *BRAF* are positively associated with homozygous *APC* loss. (B) Bar graph for Standardized Pearson residual.

Chapter 3: Single-step induction of right-side colon cancer phenotype by *BRAF*^{V600E} through acquired Wnt activation

3.1. Introduction

A major question in cancer biology is how distinct cancer phenotypes evolve within the same organ system. In this regard, sporadic colorectal adenocarcinomas (CRC) differ in their phenotypes between right and left sided tumors (Ensari et al., 2010; Jass, 2007; Jorissen et al., 2015; Li and Lai, 2009; Pai et al., 2012). While both types of tumors evolve as progression from benign adenomas to carcinomas, their molecular and pathological features are distinct from one another. It is much more common that left-sided CRCs have chromosomal instability (CIN), much less mutational burden, particularly with regards to not manifesting mismatch repair deficiencies (microsatellite stable, MSS) and less DNA methylation in promoter CpG island classified as non-CpG island methylator phenotype (CIMP-N) (Ensari et al., 2010; Jass, 2007; Jorissen et al., 2015; Pai et al., 2012; Weisenberger et al., 2006). Pathologically, the left-sided CRCs arise from conventional adenomas such as tubular or villous adenomas (Li and Burgart, 2007). On the contrary, right-sided CRCs have a tendency to have no CIN phenotype, higher mutational burden with regard to mismatch repair deficiencies (microsatellite instable, MSI) due to epigenetic silencing of *MLH1* gene and much more prevalent CpG island DNA methylation classified as CIMP-H/L (Fearon, 2011; Jass, 2007; Li and Lai, 2009; Toyota et al.,

1999; Weisenberger et al., 2006). In terms of pathological features, the right-sided tumors originate from serrated polyps such as sessile serrated adenoma (SSA) or traditional serrated adenoma (TSA) and tend to develop mucinous adenocarcinomas (Li and Burgart, 2007). Different genetic mutational landscapes exist for the above tumors (Rad et al., 2013; Sugai et al., 2006; Yamamoto et al., 2012). The left sided tumors mostly have inactivating mutations or deletions of *APC*, leading to overactivity for Wnt signaling and have frequent activating *KRAS* mutations, 18q loss and inactivating *p53* mutations (Fearon, 2011). In contrast, the right-sided tumors frequently have activating *BRAF* mutations, mostly *BRAF*^{V600E} mutation and less frequent inactivating mutations or deletions of *APC* as discussed in Chapter 2 (Fearon, 2011; Toyota et al., 1999; Weisenberger et al., 2006; Yamamoto et al., 2012).

It is well accepted that early Wnt activation by *APC* mutations, plus the co-occurring early *KRAS* mutations provide the prime driving events for evolution of left-sided CRCs (Murakami et al., 2015). Importantly, recent mouse models suggest that the *KRAS* mutations provide their role virtually always in the context of co-occurring inactivating mutations of *APC*, *p53* and *SMAD4* (Drost et al., 2015; Matano et al., 2015). Mouse models for *BRAF* mutations, in contrast, suggest that these alone lead to small intestinal (Carragher et al., 2010) and colon carcinomas (Rad et al., 2013), but the mechanisms are much less clear than for the above events for the left-sided lesions. Precisely how the Wnt pathway is involved, and how CIMP arises is not known and the latter abnormality could be a key event

since among the genes that are abnormally silenced in the association with CIMP are those that have a normal role in suppressing Wnt signaling such as SFRP1 and SFRP2 (Baylin and Ohm, 2006; Hinoue et al., 2009; Suzuki et al., 2004).

The recent development of three dimensional (3D) intestinal organoids culture has made it possible to recapitulate the *in vivo* intestinal epithelial structure *in vitro*. These organoids consist of villus-like cystic structure and crypt-like structures budding outward (Date and Sato, 2015). Similar to the cellular hierarchy *in vivo*, the intestinal stem cells and Paneth cells locate at the bottom of the crypt-like budding structures, whereas differentiating epithelial cells migrate to the central cystic structure (Date and Sato, 2015; Sato et al., 2011). In addition, the organoids recapitulate a normal process of continual cell turnover: stem cells in the budding structure continue to divide and the progenitors differentiate while migrating to the central cyst structure and undergo apoptosis as they reach terminal differentiation. Therefore, the organoids can be maintained indefinitely without artificial immortalization process (Date and Sato, 2015; Sato et al., 2011).

To enhance understanding of the functional implications of *BRAF* and *KRAS* mutations in the evolution of the distinct molecular and pathological phenotypes of CRC including epigenomic landscape, we developed a 3D organoid culture model harboring inducible *BRAF*^{V600E} or *KRAS*^{G12D} mutations and closely investigated early changes in cellular behavior and molecular profiles including DNA methylation and gene expression.

3.2 Results

3.2.1 Generation of proximal colon organoids with inducible mutations of *BRAF*^{V600E} or *KRAS*^{G12D}

To investigate the functional implication of *KRAS*^{G12D} and *BRAF*^{V600E} in colon tumorigenesis, Cre-inducible *BRAF*^{V600E}, *KRAS*^{G12D} and wild type colon organoid lines were established from mice heterozygous for *BRAF*^{V600E} (termed *BRAF*^{+/LSL}) or heterozygous for *KRAS*^{G12D} (termed *KRAS*^{+/LSL}) or wild type for both proteins (WT) respectively (Figure 3.1, A and B). Both *BRAF*^{+/LSL} and *KRAS*^{+/LSL} organoids carry the corresponding targeted insertion of a mutant exon preceded by loxp flanked STOP cassette with polyadenylation sequence. Thus, the alleles do not express the mutant genes until Cre-mediated recombination of the loxp sites is instituted (Dankort et al., 2007; Jackson et al., 2001). In addition, both mouse strains were bred to carry Cre-inducible tdTomato which is used as surrogate marker for Cre-mediated recombination (Figure 3.1, C and D). The organoids were isolated from proximal 2.5 cm of mouse colon (Figure 3.1E).

Cre-mediated activation of the oncogenes (*BRAF*^{CA}, *KRAS*^{CA}) was achieved by lentiviral delivery of constitutively expressed Cre with a hygromycin selection marker (Figure 3.1F), while infection with lentivirus encoding only the selection marker served as a control (EV) (Figure 3.1F). Before Cre-mediated induction, the *BRAF*^{+/LSL} and *KRAS*^{+/LSL} organoids, identically to wild type (WT) organoids express only wild type BRAF and KRAS proteins, and are thus identical to the

wild type organoids. After expression of Cre, the *BRAF*^{CA} and *KRAS*^{CA} organoids express one copy of the wild-type protein and one copy of the respective mutant protein, along with tdTomato, while the WT organoids express only tdTomato (Figure 3.1D).

3.2.2 *BRAF*^{V600E} and to a lesser extent, *KRAS*^{G12D} induce spheroid formation and inward polypoid growth

Immediately after Cre expression and hygromycin-selection, both the *BRAF*^{CA} and *KRAS*^{CA} organoids grow as cystic spheroid with a smooth periphery and clear lumen (Figure 3.2, C and D). The WT and EV control organoids (*BRAF*^{EV}) have the typical structures previously defined with stem cell containing, intestinal crypt-like structures as buds on the outer surface of the central cystic structures, more mature intestinal cells in the central cystic structure, and a lumen-like structure with many dying mature cells modeling the course of generation and cell death that rapidly occurs in the intestine (Figure 3.2, A and B) (Date and Sato, 2015; Onuma et al., 2013). Within 11 weeks, a high frequency of spheroid structures is observed for each expressed mutation (88.5% for *BRAF*^{CA} and 84.7% for *KRAS*^{CA}) (Figure 3.2E).

Despite that induction of both *KRAS* and *BRAF* mutations produced the above spheroidal growth of the organoids, important characteristics of the latter emerged which suggested more evolution towards having neoplastic properties. While WT and *BRAF*^{EV} organoids in culture and in H&E staining show the typical

crypt-like buddings growing outwards (Figure 3.3, A and B) (Date and Sato, 2015), these structures grow inwards for the *BRAF* mutant organoids (*BRAF*^{CA}) indicating polypoid growth with dysplastic changes (Figure 3.3, C and D). Similar polypoid growth has been reported in *APC* knock out mutant organoids (Li et al., 2014). The cells in the *BRAF*^{CA} organoids also show other dysplastic changes such as high nuclear to cytoplasm ratio and atypical columnar changes (Figure 3.3C). The *KRAS*^{CA} organoids much less frequently show the polypoid growth into the lumen (Figure 3.3E), and for the most part grow as cystic structures with a clear lumen (Figure 3.3F). The above spheroidal structures are characteristic of CRC organoids with introduced *APC* mutations, which drive, in primary CRC and in the organoids, oncogenic Wnt autonomous signaling (Drost et al., 2015; Matano et al., 2015; Onuma et al., 2013).

3.2.3 *BRAF*^{V600E} promotes acquisition of stem cell niche factor growth independency and maintenance of stemness in the organoids

Pursuant to the above data, we investigated stem cell niche factor dependency of the organoids by culturing them for three weeks in five different media conditions including fully factor ENSW media, partially deficient media such as NSW, NS and N and fully deficient Base media (Figure 3.4A). The full support media for normal organoids contains, in addition to the Wnt activators (R-Spondin1 and Wnt3a), other stem cell niche growth factors such as Noggin and EGF (Figure 3.4B). By 5 months of growth, only *BRAF*^{CA} organoids acquired

the property to grow in base media, which completely lacks of all four niche factors used to support stemness and growth of WT organoids including any of Wnt activators (Figure 3.4C) (Date and Sato, 2015; Sato et al., 2011; Sato et al., 2009). Among all of our organoid cultures, the *KRAS*^{CA} and WT organoids derived at 2 months post Cre-induction are independent of EGF but require Wnt3a, R-spondin1 and Noggin (Figure 3.4C) to sustain their growth for three weeks. However, *BRAF*^{CA} organoids at 2 months is independent of Wnt3a in addition to EGF although R-spondin1 and Noggin are required (Figure 3.4C). As above, at 5 months, *KRAS*^{CA} (*KRAS*^{CA1} and *KRAS*^{CA2}) and wild type organoids (WT, *BRAF*^{EV1}, *BRAF*^{EV2} and *BRAF*^{EV3}) still require R-spondin1 and Noggin to sustain their growth and stemness (Figure 3.4C). The independent organoids from three *BRAF*^{CA} replicates were continuously cultured in base, factor free media and three separate *BRAF*^{CA-IND} replicates are established from the culture. The polypoid growth observed previously in *BRAF*^{CA} organoids (Figure 3.3, C and D) is now even more prominent in the *BRAF*^{CA-IND} organoids, indicating a progressive accumulation and selection of dysplastic cells in Base medium (Figure 3.5A). The multi-layered polypoid growth in the *BRAF*^{CA-IND} fills up the lumen, which otherwise in WT or EV organoids consists of many dead cells (Figure 3.5, A and B).

We next find that the above niche-factor independency, and autonomous Wnt signaling of *BRAF*^{CA-IND} organoids is due to cell intrinsic mechanisms and not secretion of Wnt3a from Paneth cell or Paneth-like cells in the *BRAF*^{CA-IND}

organoids. Thus, when equal proportions of *BRAF*^{CA-IND} organoids were co-cultured for one week in Base media and ENSW media with *BRAF*^{EV} or *KRAS*^{CA} organoids (Figure 3.6A), only the recombined *BRAF*^{V600E} allele originating from *BRAF*^{CA-IND} was detected in both ENSW and Base media culture (Figure 3.6B). In contrast, *BRAF*^{EV} or *KRAS*^{CA} existed only in the full ENSW medium but not in Base media as indicated by the presence of recombined and non-recombined *BRAF*^{V600E} alleles or the recombined *KRAS*^{G12D} allele in the respective co-cultures in ENSW media not in Base media (Figure 3.6B). Moreover, tdTomato+ *BRAF*^{CA-IND} and tdTomato- *BRAF*^{EV} organoids were observed in ENSW media but in Base medium only tdTomato-positive *BRAF*^{CA-IND} organoids survived (Figure 3.6A).

To further pursue the conclusions that *BRAF*^{CA} organoids have acquired autonomous Wnt-activation rendering them independent of Wnt in the medium, we used porcupine inhibitor IWP2 to further clarify the scenario. Palmitoylation of Wnt ligand by Porcupine (Porcn) is a critical step for Wnt secretion and subsequently action of Wnt ligands on their receptors (Chen et al., 2009). The IWP2 will prevent secretion of Wnts from any type of cells and their subsequent paracrine or autocrine action (Figure 3.7, A and B). In this experiment, the organoids are treated with IWP2 in NS media, which is deficient of external Wnt3a (Figure 3.7B). The IWP2 completely inhibit growth of WT and *BRAF*^{EV} at low dose of 2.5mM (Figure 3.7B). *KRAS*^{CA} replicates are slightly resistant to IWP2 but their growth is inhibited more than 50% at higher dose of 10mM (Figure 3.7B). Two *BRAF*^{CA} replicates also have partial resistance as *KRAS*^{CA} but

the other one replicate is completely resistant to IWP2 (Figure 3.7B). Moreover, all *BRAF^{CA-IND}* replicates are completely resistant to IWP2 indicating that they are enriched for organoids that are completely autonomous and independent of external Wnt signaling.

3.2.4 A single step transformation by *BRAF^{V600E}* induces right-sided CRC phenotype forming invasive mucinous adenocarcinomas

All the above results indicate that *the BRAF^{CA} organoids* have abnormal and aggressive growth properties and independency to environmental signalings hinting that these cells are transformed by *BRAF^{V600E}* alone. To test if this indeed is the case, we performed xenograft assay in NOD *scid* gamma immunodeficient mice (NSG). All wild type organoids, WT and *BRAF^{EV}1-3*, and the *KRAS^{CA}1-2* organoids didn't form any tumors in the NSG mice. In contrast, *BRAF^{CA}1*, *BRAF^{CA}3*, *BRAF^{CA-IND}1-3* formed tumors in all injection sites although the size of tumor and growth rate were variable within and between the samples (Figure 3.8A). Grossly, the tumors were gelatinous with copious amount of mucin (Figure 3.8B). Histologically, the tumors display features of mucinous carcinomas with dysplastic changes. The tumors consist of mucin filled cysts lined by dysplastic epithelial cells displaying piled up cells, high nuclear to cytoplasm ratio, bizarre looking mitotic figures and multinucleated cells (Figure 3.8B). A fair number of goblet cells spread between the epithelial cells. Signet rings, a pathognomonic feature of mucinous carcinoma, also are observed in the tumors (Figure 3.8B).

CHAPTER 3. SINGLE-STEP INDUCTION OF RIGHT-SIDED COLON CANCER PHENOTYPE BY *BRAF*^{V600E} THROUGH ACQUIRED WNT ACTIVATION

These morphological features are also observed in human mucinous colon adenocarcinomas as shown here in Figure 3.8, A and B.

In addition, two injection sites of BRAF^{CA-IND1} and 3, formed tumor which invaded into the peritoneum. One of these xenografts also resulted in a tumor infiltrating the kidney capsule (Figure 3.9A). Both tumors in subcutaneous and kidney capsule shared the same features of dysplasia and mucinous characteristics (Figure 3.9C). The integrity of muscle layer between the tumors inside and outside was disrupted with tumor cells seeded between the muscle fibers (Figure 3.9 C). The ability of tumor cells to survive in blood stream and metastasize to distal regions is also verified by formation of xenograft tumor after tail vein injection of single cells of BRAF^{CA-IND1} (Figure 3.9B). Thus, the cells from BRAF mutant organoids were able to survive in the blood stream, extravasate from the vessel and grow as a tumor outside of the blood stream (Figure 3.9B). The xenograft tumor formation indicates that BRAF^{CA} organoids are capable to make an invasive mucinous adenocarcinoma, which is frequently found in human right-sided *BRAF* mutant CRC (Bettington et al., 2013; Nosho et al., 2008; Pai et al., 2012; Song et al., 2005; Tanaka et al., 2006). Notably in the TCGA CRC database (Figure 3.10, A and B) BRAF mutations are strongly associated with mucinous adenocarcinoma in Fisher's exact test with *p* value of 1.676e-06 (Figure 3.10A)

3.2.5 *BRAF^{V600E}* organoids promotes sustained up-regulation of intestinal stem cell and proliferation genes and intestinal Wnt targets during deprivation of all stem cell niche factors.

To investigate how the *BRAF^{CA}* organoids were able to survive without stem cell niche factors, gene expression profiling was performed in WT, *BRAF^{EV}*, *BRAF^{CA}*, *BRAF^{CA-IND}* and *KRAS^{CA}* organoids grown in two different media conditions, ENSW and Base media for 48hr (Figure 3.11A). In ENSW media condition, the *BRAF^{CA}* and *BRAF^{CA-IND}* organoids show a very similar gene expression pattern as WT, *BRAF^{EV}* and *KRAS^{CA}* organoids. This is probably due to prevailing activation of Wnt and others pathways by stem cell niche factors in ENSW media (Sato et al., 2009). In contrast, the *BRAF^{CA}* and *BRAF^{CA-IND}* organoids show very distinct gene expression pattern from WT, *BRAF^{EV}* and *KRAS^{CA}* organoids in Base media. Firstly, with the gene expression pattern from those organoids in Base media, Gene Set Enrichment Analysis(GSEA) with Hallmark gene sets (Figure 3.11B) indicates that *BRAF^{CA}*, *BRAF^{CA-IND}* and *KRAS^{CA}* are enriched with proliferation pathways such as E2F targets, G2M checkpoint, mitotic spindle and DNA repair and cancer related pathways including Myc targets (Figure 3.11C) and Mtorc1 signaling (Table 3.1). More interestingly, only *BRAF^{CA}* and *BRAF^{CA-IND}* organoids but not *KRAS^{CA}* organoids, are enriched for Wnt / β -catenin signaling (Table 3.1 and Figure 3.11C). To further delineate the expression patterns, the CoGAPS (Coordinated Gene Activity In Pattern Sets) algorithm was applied to the dataset to find patterns of

gene expression changes in the organoids with different genotypes (Figure 3.12, A and B) (Fertig et al., 2010; Fertig et al., 2013; Fertig et al., 2012; Fertig et al., 2014; Speier and Ochs, 2012; Stansfield et al., 2016). Four different patterns of gene expression were found (Figure 3.12C). Pattern 1 contains genes up-regulated in ENSW media and down-regulated in Base media in WT / *BRAF*^{EV}. However, the up-regulation of the gene remain in *BRAF*^{CA-IND} and *BRAF*^{CA1} even under deprivation of all niche factors (Figure 3.12C) and these genes are those up-regulated in intestinal stem cells and proliferating cells (TA cells) (Merlos-Suarez et al., 2011) and intestinal Wnt target genes (de Lau et al., 2011). Two important stem-cell marker genes, CD44 and SOX9 (Du et al., 2008; Feng et al., 2013), are among these genes and we verified their high levels by quantitative PCR (Figure 3.14, A and B). Although their expression is not sustained in *KRAS*^{CA} and the other two *BRAF*^{CA} replicates in Base media as in WT / *BRAF*^{EV}, the extent of down-regulation is less than in WT / *BRAF*^{EV} (Figure 3.12C). The pattern 2 has the opposite direction containing gene down-regulated in ENSW and up-regulated in BASE in WT / *BRAF*^{EV} (Figure 3.12C) but which remain low in *BRAF*^{CA-IND} and *BRAF*^{CA1} during deprivation of all factors (Figure 3.12C). These genes are those normally up-regulated in differentiated epithelial cells (Merlos-Suarez et al., 2011) (Figure 3.13B). Pattern 3 and 4 contain genes with high expression in WT / *BRAF*^{EV} (Figure 3.12C). Pattern 4 genes have high expression in *BRAF*^{CA-IND} and low expression in WT / *BRAF*^{EV} (Figure 3.12C).

3.2.6 *BRAF^{V600E}* organoids exhibit sustained up-regulation of intestinal stem cell population

In addition to the gene expression pattern outlined in the preceding section, increased stemness in *BRAF^{CA-IND}* was also confirmed by flow cytometry assay for CD44, which is a stem-cell marker (Du et al., 2008; Kuhnert et al., 2004). In organoids grown in ENSW, the CD44 positivity was highest in *BRAF^{CA-IND}*, followed by *BRAF^{CA}*, *KRAS^{CA}* and WT (Figure 3.15 A and C). On average, about 39% of cells in *BRAF^{CA-IND}*, 25% of cells in *BRAF^{CA}*, 22% of cells in *KRAS^{CA}* and 1.6% of cells in WT were CD44 positive (Figure 3.15 A and C). Upon deprivation of stem cell niche factors, the number of CD44+ stem cells in *BRAF^{CA}* and *KRAS^{CA}* was further decreased to 12% and 4% on average, respectively (Figure 3.15 B and C) and in WT, to below 1% (Figure 3.15 B and C). In contrast, CD44+ stem cell population in *BRAF^{CA-IND}* was increased in all three replicates upon deprivation of the niche factors (Figure 3.15 B and C) to an average of around 60% in *BRAF^{CA-IND}* in Base media (Figure 3.15 B and C). Thus, the data above show that in contrast to the dynamic regulation of stemness and differentiation genes in WT, *KRAS^{CA}* and *BRAF^{CA}* organoids in response to the deprivation of niche factors, expression of these genes is stably maintained in *BRAF^{CA-IND}* in a pattern reflecting pro-stemness and anti-differentiation.

3.2.7 *BRAF^{V600E}* exhibit similar methylation profile as human right-sided CRC including presence of CIMP and increased methylation of

**genes for stemness, differentiation maintenance and regulation of the
Wnt pathway**

Right sided human CRCs with *BRAF*^{V600E} mutations frequently have an important epigenetic characteristic termed the gene promoter, CpG island DNA hypermethylation phenotype or CIMP positive (Bettington et al., 2013; Burnett-Hartman et al., 2013; Hinoue et al., 2012; Hinoue et al., 2009; Hughes et al., 2012; Hughes et al., 2013; Jass, 2007; Kambara et al., 2004; Kriegl et al., 2011; Lee et al., 2008; Nosho et al., 2008; O'Brien et al., 2006; Ogino et al., 2006; Pai et al., 2012; Phipps et al., 2015; Silva et al., 2014; Song et al., 2005; Sugai et al., 2006; Tanaka et al., 2006; Toyota et al., 1999; Weisenberger et al., 2006; Yamamoto et al., 2012; Yang et al., 2004). In contrast, the-left sided tumors with frequent *KRAS*^{G12D/V} mutations are associated with CIMP- and CIMP-intermediate groups (Bettington et al., 2013; Burnett-Hartman et al., 2013; Hinoue et al., 2012; Hinoue et al., 2009; Hughes et al., 2012; Hughes et al., 2013; Jass, 2007; Kambara et al., 2004; Kriegl et al., 2011; Lee et al., 2008; Nosho et al., 2008; O'Brien et al., 2006; Ogino et al., 2006; Pai et al., 2012; Phipps et al., 2015; Silva et al., 2014; Song et al., 2005; Sugai et al., 2006; Tanaka et al., 2006; Toyota et al., 1999; Weisenberger et al., 2006; Yamamoto et al., 2012; Yang et al., 2004). Why the right-sided *BRAF*^{V600E} tumors have CIMP and whether this epigenetic abnormality is a “driver versus passenger” event for evolution of these cancers has not been clarified. Thus we tested for methylation differences among the WT, *KRAS*^{CA}, *BRAF*^{FEV}, *BRAF*^{CA} and *BRAF*^{CA-IND} organoids. One replicate of

each was subjected to a genome-wide methylation analysis at 5 months after induction of mutations using MBD-seq (Figure 3.16A) (Guerrero-Preston et al., 2014). The result indicates that CIMP is a feature of our *BRAF* mutant organoid model and many of the involved genes are those that may play an essential driver role in cells escaping from senescence, stem cell features, lack of differentiation and especially Wnt autonomous signaling. Thus, as compared to WT and empty vector control *BRAF*^{EV} organoids, there is increased DNA methylation of normally unmethylated promoter CpG islands of ~ 225 genes at 5 months in *BRAF*^{CA} organoids with even more, ~ 500 in *BRAF*^{CA-IND} organoids while only 20-50 such genes exist in *KRAS*^{CA} organoids (Figure 3.17A). KEGG gene ontology analysis of these genes differentially methylated in *BRAF*^{CA-IND} revealed Wnt signaling as the second most significant pathway enriched following melanogenesis which is also driven by a Wnt signature (Figure 3.17B). Thus the sustained stem cell features and autonomous Wnt activation accompanying induction of *BRAF*^{V600E} might well be due to epigenetic modulation of Wnt pathway. The methylation patterns for individual Wnt genes are shown in Figure 3.18A with hypermethylation seen for important Wnt negative regulators, including *Sfrp1 and 2*, *Hic1*, *Wt1*, *Sox7*, *Sox17*, *Frzb* and *Cdh2* in *BRAF*^{CA-IND} organoids and partially in *BRAF*^{CA} but not in WT and *KRAS*^{CA} organoids (Figure 3.18A). All of these genes are methylated in CIMP CRC (Hinoue et al., 2012; Hinoue et al., 2009; Toyota et al., 1999; Weisenberger et al., 2006; Yamamoto et al., 2012). In addition, there is increased DNA methylation in other CIMP genes

such as *Socs1*, *Gata3*, *Galnt4*, *Fzd10*, *Cdkn2a* and *Igfbp7* (Figure 3.18B). Of these, epigenetic suppression of *Cdkn2a* (Carragher et al., 2010) and *Igfbp7* (Wajapeyee et al., 2010) were previously reported to play a critical role in escape from oncogene induced senescence. The methylation of these two genes in *BRAF*^{CA-IND} correlates well with the previous reports and explains why *BRAF*^{CA-IND} organoids may not show any signs of senescence. Lastly, very important genes which normally are expressed to control intestine differentiation, including *Bmp4* and *Bmpr1b* are abnormally methylated as well in *BRAF*^{CA-IND} organoids and partially in *BRAF*^{CA} organoids (Figure 3.18C). As discussed in section 3.2.5 and 3.2.6, stem cell gene expression signature and high stem cell population characterize *BRAF*^{CA-IND} organoids and also, partially in *BRAF*^{CA} organoids and each of the above silenced genes may play important roles in these phenotypic features. For example, without Noggin added to the media, BMP4 should have induced differentiation through inhibition of Wnt signaling (Foulke-Abel et al., 2016; He et al., 2004; Mahe et al., 2015; Saxena et al., 2016; Zachos et al., 2016).

3.3 Discussion

This work shows that, unlike *KRAS*^{G12D}, *BRAF*^{V600E} mutation drives stem cell niche factor independent growth and tumorigenic transformation in colon organoids. These properties are acquired through accumulation of DNA methylation in Wnt negative regulators, CIMP genes including cell cycle check point genes, genes that induce differentiation, and genetic mutations in Wnt

activators such as b-catenin. Importantly, transformation of organoids by *BRAF*^{V600E} recapitulates human *BRAF* mutant tumors in terms of molecular changes and morphological features. Thus the data in this thesis shows that in the serrated pathway to colon cancers, *BRAF*^{V600E} mutation alone induces and selects for a combination of key epigenetic and genetic alterations that lead to acquisition of Wnt pathway activation and stemness (Figure 3.19).

The major observation here that *BRAF*^{V600E} causes a gradual acquisition of Wnt independency presents novel molecular insights into the alternate or sessile-serrated pathway to CRC. The serrated pathway has been invoked to explain non-*APC* mutant CRCs which do not fit with the classical pathway model known as Vogelgram (Jorissen et al., 2015). While *BRAF* mutation is highly associated with cancers in the sessile-serrated pathway, *APC* mutations are much less frequent. The observation that in one step *BRAF*^{V600E} is able to cause Wnt independency and transformation without other mutations to start with may explain why *BRAF* mutant CRCs have a tendency not to have concurrent *APC* mutation even though Wnt activation is a known characteristic of these tumors (Morkel et al., 2015; Murakami et al., 2015). The molecular changes we observe in the *BRAF*^{CA-IND} organoids, especially altered epigenetic and genetic changes involved in Wnt activation, appears to provide a basis for how *BRAF*^{V600E} results in CRC in the absence of starting Wnt activating mutations. In this context, the data here supports the study by Rad and colleagues which showed that activation of *BRAF*^{V600E} in mouse intestine caused adenomas and carcinomas, about a third of

which can be attributed to mutations in Wnt pathway genes, including β -catenin (Rad et al., 2013). In contrast, the classical CRC pathway generally begins with Wnt activation by mutations in *APC*, followed by activation of *KRAS*. Previous studies have shown that *APC* knock out or knock down can make organoids independent to Wnt3a and R-spondin and induce them to form tumors in conjunction with other mutations such as activating *KRAS* mutation, inactivating *p53* and *SMAD4* mutations (Li et al., 2014; Matano et al., 2015). Further, a small group of serrated CRCs have *KRAS* mutations, and do not activate the Wnt pathway, but are dependent on inactivation of p16^{Ink4a}/Rb pathway (Bennecke et al., 2010). Thus our studies in conjunction with the other studies discussed above shows that although activating mutations in *KRAS* and *BRAF* are key driver mutations of CRCs, *BRAF* activating mutation in the colon epithelial stem cell niche causes distinct epigenetic and genetic changes, the key result of which is Wnt activation, helping to explain the sessile-serrated route to CRC.

The observation that *BRAF*^{V600E}, but not *KRAS*^{G12D}, causes stem cell niche factor independent growth and transformation is intriguing given that both mediate their effect through activating the RAS-RAF-MEK signaling pathway. Most importantly, genome-wide DNA methylation analyses shows DNA methylation of normally unmethylated promoter CpG islands for ~ 225 genes at 5 months in *BRAF*^{CA} organoids with even more, ~500 in *BRAF*^{CA-IND} organoids, while only 20-50 such genes in *KRAS*^{CA} organoids are affected as compared to WT organoids. Thus, this epigenetic change appears to not only evolve after

induction of *BRAF*^{V600E} but to be further selected in *BRAF*^{CA-IND} cells. Furthermore, the involved genes are highly represented in the CIMP+ marker genes for human right-sided CRC as found in TCGA analyses. The genes methylated in *BRAF*^{CA-IND} organoids, include negative regulators of Wnt such as *Sfrp1*, *Sfrp2*, *Hic1*, *Wt1*, *Sox7*, *Sox17*, *Frzb* and *Cdh2*, while *KRAS*^{G12D} organoids do not show methylation at these genes. The differential effect of *BRAF*^{V600E} and *KRAS*^{G12D} on inducing the epigenetic alteration is not only relevant to the tumorigenesis process, but also extremely important in terms of the mechanisms involved in methylation of the promoter CpG islands. Previous studies have causally implicated both *KRAS* (Serra et al., 2014) and *BRAF* (Fang et al., 2014) in mediating the CIMP phenotype through two different proteins, ZNF304 and MAFG, respectively. However, these experiments have been performed in cancer cell lines, which already have high level of DNA methylation. Further, our studies here and the inferred relation between CIMP and *BRAF* or *KRAS* mutations in CRCs from TCGA data and other clinical studies (Hinoue et al., 2012; Hinoue et al., 2009; Hughes et al., 2012; Hughes et al., 2013; Jass, 2007; Kambara et al., 2004; Lee et al., 2008; Nosho et al., 2008; Sugai et al., 2006; Tanaka et al., 2006; Toyota et al., 1999; Weisenberger et al., 2006; Yang et al., 2004) (Figure 3.18B) suggest a dominant role for *BRAF* in inducing the CIMP phenotype. The exact mechanism underlying the gradual accumulation of methylation in *BRAF*^{CA} and *BRAF*^{CA-IND}, but not *KRAS*^{CA} organoids, need to continue to be investigated. Our organoid model developed here will be invaluable to study the mechanisms

mediating the differential effect of mutant *BRAF* and *KRAS* on modulating the epigenome in a natural and non-transformed cellular context rather than transformed cancer cells.

Our present study has major implications in understanding and treating human right-sided CIMP positive CRCs. The stem cell niche factor independent *BRAF* organoids recapitulate many features of right-sided CIMP positive *BRAF* mutant CRCs. Non-*APC* mutant / *BRAF* mutant tumors tend to be mucinous adenocarcinoma in human (Bettington et al., 2013; Nosho et al., 2008; Pai et al., 2012; Song et al., 2005; Tanaka et al., 2006) (Figure 3.10 A and B). Subcutaneous xenografting of *BRAF*^{CA} and *BRAF*^{CA-IND} organoids resulted in mucinous adenocarcinoma highlighted by signet ring and formation of mucin filled glandular cysts. This category of right-sided human CRCs, which also display MSI (microsatellite instable), have recently been shown to have increased T cell infiltration and better prognosis to immunotherapy (Le et al., 2015). However, MSS tumors with *BRAF* mutations have the worst prognosis (Jorissen et al., 2015). There have been controversies over whether the increased T cell infiltration is due to higher number of neoantigen generated from the high mutational burden in *BRAF* mutant MSI tumors or overall cellular stress due to increased mutation in the MSI tumors. Our organoid model, with appropriate manipulations to inactivate *Mlh1* to create the MSI phenotype, can be used to address the interaction between the immune system and the tumor cells in an immunocompetent syngeneic xenograft or orthotopic transplantation model.

Finally, the ability for $BRAF^{V600E}$ to cause transformed phenotype in the absence of a microenvironment deserves special mention. The original inducible construct for our model was first engineered for internal expression throughout the mouse intestine and we induced the mutation in this setting as well. In contrast to the results in our organoid model, with induced transformation in 2-5 months, we observed only hyperplastic growth in the colon epithelium up to about 6 months after $BRAF^{V600E}$ induction in LGR5+ stem cells or CDX2+ colonocytes. The mice develop severe skin lesions and other tumors beyond this point so they could not be monitored further. In the $BRAF$ mutation mouse model, it takes a prolonged period of greater than a year to form colon adenomas (Rad et al., 2013). Thus the native colonic setting of the crypts and the microenvironment appears, at least initially to be anti-tumorigenic, and this fact accentuates our findings for the intrinsic pathway signaling and tumorigenesis of $BRAF^{V600E}$ in the *ex vivo* organoid setting. Key questions thus will be how the microenvironment prevents tumorigenesis. It is already known that stroma can have suppressive role in tumorigenesis that can be mediated through Hedgehog signaling pathway (Shin et al., 2011; Vaegler et al., 2012) and other pathways. The accentuated tumorigenesis we see in our organoid culture could be due to the absence of stromal interaction. The effect of interaction between epithelial cells and stroma can be investigated with the organoid model in conjunction with an organoid / stroma co-culture model (Figure 3.20).

3.4 Material and Methods

3.4.1 Mouse breeding and animal experimentation

All animal experiments were implemented in accordance with an animal protocol approved by the Johns Hopkins University Animal Care and Use Committee (Protocol# MO10M388). All the mice were housed in Helicobacter negative and SPF (Specific Pathogen Free) environment.

Homozygous tdTomato reporter (B6;129S6-Gt(ROSA)26Sor^{tm9}(CAG-tdTomato)Hze/J) mouse was bred with heterozygous inducible *BRAF* mouse (B6.129P2(Cg)-Braf^{tm1Mmcm}/J) or heterozygous inducible *KRAS* mouse (B6.129S4-Kras^{tm4Tyj}/J) to generate mice that are heterozygous *BRAF* with heterozygous tdTomato reporter, heterozygous *KRAS* with heterozygous TomatoRed reporter and wild type with heterozygous TomatoRed.

3.4.2 Isolation of crypt cells from colon

Male mice from each genotype between the age of 35 days and 40 days were euthanized by carbon dioxide and subjected to a necropsy. The first 2 cm of proximal colon is collected from the mice. The collected colons were washed 5 times with sterile Complete Chelating Solution (CCS: 5.6mM Na²HPO₄, 8mM KH₂PO₄, 96.2mM NaCl, 1.6mM KCl, 43.4mM Sucrose, 54.9mM D-Sorbitol and 0.5mM DL-dithiotriteritol and incubated in sterile CCS with cocktail of antibiotics: Primocin (Invivogen ant-pm-1) and Normocin (Invivogen ant-nr-1) for 30 minutes in 4°C. The clean proximal colons were incubated in CCS with 2mM

EDTA for 20 minutes at 37°C to release crypt from the tissue. After incubation, the crypts on the proximal colon were gently scraped with cell scraper to collect crypts. The crypts were collected with CCS with EDTA in 15ml tubes and the tubes were centrifuged at 300g for 10 minutes. Subsequently, the crypt pellets were washed with CCS with cocktail of antibiotics for 4 times by repeated resuspension and centrifugation. After the serial washing, the crypts were resuspended in growth factor reduced phenol red free Matrigel® (Corning® #356231) and plated on regular cell culture plates.

3.4.3 Organoids culture

The plated organoids were cultured with ENSW culture media made of 50% of Wnt3a conditioned media, 20% of R-Spondin conditioned media, 20% of Advanced DMEM/F12 (Invitrogen® 12634-010) with 1% Pen strep® (ThermoFisher® 15140148), 10mM HEPES, 2mM L-glutamine and B27 (Invitrogen® 17504044), 10% of Noggin conditioned media and 100ng/ml of EGF(R&D systems 236-EG-200). The conditioned media for Wnt3a, R-Spondin and Noggin were made as described previously (Matano et al., 2015; Sato et al., 2011; Sato et al., 2009). NSW media was made with 50% of Wnt3a conditioned media, 20% of R-Spondin conditioned media, 20% of Advanced DMEM/F12 (Invitrogen® 12634-010) with 1% Pen strep® (ThermoFisher® 15140148), 10mM HEPES, 2mM L-glutamine and B27 (Invitrogen® 17504044), 10% of Noggin conditioned media. NS media was made with 50% of DMEM with 10% FBS, 20%

of R-Spondin conditioned media, 20% of Advanced DMEM/F12 (Invitrogen® 12634-010) with 1% Pen strep® (ThermoFisher® 15140148), 10mM HEPES, 2mM L-glutamine and B27 (Invitrogen® 17504044), 10% of Noggin conditioned media. N media was made with 50% of DMEM with 10% FBS, 20% of Advanced DMEM/F12 with 1% Pen strep® (ThermoFisher® 15140148), 10mM HEPES and 2mM L-glutamine, 20% of Advanced DMEM/F12 (Invitrogen® 12634-010) with 1% Pen strep® (ThermoFisher® 15140148), 10mM HEPES, 2mM L-glutamine and B27 (Invitrogen® 17504044), 10% of Noggin conditioned media. Base media was made with 50% of DMEM with 10% FBS, 30% of Advanced DMEM/F12 with 1% Pen strep® (ThermoFisher® 15140148), 10mM HEPE and 2mM L-glutamin, 20% of Advanced DMEM/F12 (Invitrogen® 12634-010) with 1% Pen strep® (ThermoFisher® 15140148), 10mM HEPES, 2mM L-glutamine and B27(Invitrogen® 17504044).

3.4.4 Subcloning of lentivirus plasmid and packaging of lentivirus

Puromycin resistance gene in Puro.Cre empty vector (Addgene #17408) was replaced by hygromycin resistance gene PCR amplified from pBABE-hygro-hTERT (Addgene #1773) using primer listed below (Hyg F and R) by Gibson Assembly® cloning kit (NEB® #E5510S) generating Lenti-cre vector. Subsequently, Cre in the Lenti-cre vector was deleted by Gibson Assembly® cloning kit generating Lenti-empty vector using primers listed below (Cre deletion F and R).

CHAPTER 3. SINGLE-STEP INDUCTION OF RIGHT-SIDED COLON CANCER
PHENOTYPE BY *BRAF*^{V600E} THROUGH ACQUIRED WNT ACTIVATION

Hyg F: TAACGCGCTAGCAAAGATGAAAAAGCCTGAACTCAC

Hyg R: GTAGAATGCGGCCGCCTATTCCTTTGCCCTCGG

Cre deletion F : CCGTAACCTGGATAGTGAAAC

Cre deletion R : CCTTCCTCTTCTTCTTGGG

Lentivirus was produced in Lenti-X™ 293T cell line transfected with Packaging vectors and Lenti-cre or Lenti-empty mixed with Xfect™ polymer. 72hr after the transfection, the media is collected and concentrated using Lenti-X™ concentrator.

3.4.5 Transduction of organoids with lentivirus

Organoids were collected from Matrigel® (Corning® #356231) using Cell Recovery solution (Corning® #354253). Organoids were broken into small piece of cells by repeated pipetting. The small pieces of cells were digested by 2U/ml of Dispase I for 20 minute at 37°C. Matrigel® is spread on the 12 well surface and the plate is incubated at 37°C to polymerize for 10 minutes. The digested organoids are mixed with virus and 8ug/ml Polybrene® (Sigma-Aldrich® #107689) in ENSW organoid culture media and plated on the solidified Matrigel®. After 24 hour, the media is removed and Matrigel® is spread on the organoids.

3.4.6 DNA/RNA isolation

Organoids were collected from Matrigel® (Corning® #356231) using Cell Recovery solution. The collected organoids were broken into small pieces of cells by repeated pipetting and incubated in 15ml ice cold media for 30min letting live cells precipitate. Live cells in bottom 3ml were recovered and mixed again with 12ml of media for second precipitation. After second precipitation, bottom 2ml of the media was collected and centrifuged at 1,000g for 1minute to make a pellet. From the pellet, DNA/RNA was extracted using Allprep kit mini or micro (Qiagen).

3.4.7 Recombination specific PCR and genotyping

Mouse genotypes were determined by standard PCR of tail DNA. *BRAF* genotype and recombination is determined by a primer set of *BRAF* Fwd (5'-TGA GTA TTT TTG TGG CAA CTG C-3') and *BRAF* Rev (5'-CTC TGC TGG GAA AGC GGC-3'). 185base pair, 308 base pair and 335 base pair fragments are generated from wild type allele, non-recombined mutant allele and recombined mutant allele respectively (Dankort et al., 2007). *KRAS* genotype is determined by PCR with *KRAS* mt Fwd (5'-CCA TGG CTT GAG TAA GTC TGC-3') and *KRAS* mt Rev (5'-CGC AGA CTG TAG AGC AGC G-3'). Recombination of *KRAS* mutant allele is determined by a PCR with *KRAS* 1 (5'-GTC TTT CCC CAG CAC AG TGC-3') and *KRAS* 2 (5'-AGC TAG CCA CCA TGG CTT GAG TAA GTC TGC A-3'). Recombined mutant allele generates 650base pair long fragments and wild type allele generates 622 base pair fragments with this PCR.

3.4.8 Organoid growth assay by CellTiter-Glo 3D

The organoids were collected using Cell Recovery solution (Corning #354253). The same volume of CellTiter-Glo3D® (Promega #G9681) was added to organoids suspension and mixed by vortexing at high speed for 5min. Then, the mixture was incubated for 25min at room temperature. The mixture was distributed in three wells of dark 96 well plates and its luminescence was measured by plate reader (POLARstar® Omega by BMG LABTECH)

3.4.9 Quantification of cell number for xenograft assay

The organoids were recovered from the Matrigel using Cell Recovery solution (Corning #354253). The organoids were disrupted and washed in the media 2 times to get rid of dead cells. Then, the fragmented organoids were serially diluted and each dilution was separated into two wells, one for CellTiter-Glo3D assay and the other for Quant-iT PicoGreen® ds DNA assay. The luminescence of CellTiter-Glo3D assay and fluorescence of Quant-iT PicoGreen® ds DNA assay were measured by plate reader (POLARstar® Omega by BMG LABTECH). A correlative standard curve between these two values in the serial dilution of the organoids was generated. Based on the size of mouse genome (2.8×10^9 base pairs), the amount of DNA per diploid genome is about 6 pg. Thus based on the amount of DNA, the number of cells were extrapolated for the standard curve. For organoids that were to be implanted, an aliquot of the organoids was fragmented as above and used to estimate the cell numbers using

the CellTiter-Glo3D assay and the standard curve above. Then proportions of intact organoid aliquots amounting to equal cell numbers of the different genetic backgrounds were used for implantation as described below.

3.4.10 Xenograft implantation

The organoids were recovered from the Matrigel using Cell Recovery sol (Corning #354253) without disrupting the structures. Then, using a portion of the organoids, CellTiter-Glo3D assay is performed. Using the formulation between CellTiter-Glo3D and cell number, cell number was estimated. Based on the estimation, 0.5 million cells were injected subcutaneously with 16G needle to minimize disruption of the organoid 3D structure in male NOD.Cg-Prkdc^{scid} Il2rg^{tm1Wjl}/SzJ (NSG) (JAXTM) with Matrigel. Injection sites were examined every week for tumor growth. The volume of the tumors estimated by ellipsoid volume formula.

3.4.11 Flow cytometry

Organoids were collected from Matrigel using Cell Recovery solution (Corning #354253). Organoids were broken into small piece of cells. The small piece of cells were digested by 2U/ml of Dispase I (Sigma #D4818) for 20 minute at 37°C. Digested organoids were filtered through 70um cell strainer. The single cells were stained with CD44 antibody (ThermoFisher #A161693) and 200ng/ml of DAPI for live/dead cell staining. The cells were analyzed by flow cytometry

using a DakoCytomation MoFlo at flow cytometry core of Johns Hopkins School of Public Health.

3.4.12 Quantitative RT-PCR

RNA was converted to cDNA using qscript (Quanta #95048-025) following the standard protocol. Quantitative PCR reactions were run on the cDNA samples with triplicate technical replicates using Taqman probe assays, Mm99999915_g1 for GAPDH, Mm00448840_m1 for Sox9 and Mm01277161_m1 for Cd44. GAPDH was used as an endogenous control. It is selected based on stable gene expression pattern in gene expression array.

3.4.13 Gene expression microarray

For genome-wide gene expression analysis, we carried out gene expression array at the Sidney Kimmel Comprehensive Cancer Center (SKCCC) Microarray Core at the Johns Hopkins University. Briefly, around 400ng of total RNA was reverse-transcribed into cDNA by MMLV-RT using oligo dT primer. Then from the cDNA, labeled cRNA was generated through in vitro transcription by T7 RNA polymerase in presence of labeled by Cyanine-3 labeled CTP (Perkin Elmer). The labeled cRNA was purified using Rneasy mini kit (Qiagen). 825ng of each Cy3-labeled cRNA was hybridized to Agilent mouse GF 4x44K V2 microarray (G4846A) at 65°C for 17 hours. Then, the arrays were scanned by an Agilent G2565 scanner.

Expression data were analyzed in the R/Bioconductor environment using the limma package (PMID:25605792). Briefly, expression data was normalized by quantile normalization, and the probe level information was extrapolated to gene level information by estimating the median of all probes corresponding to each gene. These gene level values were used in COGAPS analysis as described below.

3.4.14 Coordinated Gene Activity in Pattern Sets (CoGAPS) analysis

For genome-wide gene expression pattern analysis, we carried out CoGAPS analysis in collaboration with Elana Fertig as described previously (Fertig et al., 2010; Fertig et al., 2013; Fertig et al., 2012; Fertig et al., 2014; Speier and Ochs, 2012). With the list of genes in the patterns, we performed gene set enrichment using a permutation test in the CoGAPS gene set statistic (Fertig et al., 2010; Fertig et al., 2013; Fertig et al., 2012; Fertig et al., 2014; Speier and Ochs, 2012) to associate CoGAPS patterns with pathways. We further performed clustering analysis of genes determined to be uniquely associated with each pattern through a “PatternMarker” statistic. Specifically, we computed the Euclidean distance between the elements of the P matrix for a given pattern and the elements of the A matrix for a given gene. In order to account for the varying magnitude of expression across genes, the rows of both the A and P matrix are scaled to have a maximum of one. The genes were ranked within each meta-pathway by increasing distance with from its lp-norm. Unique sets of marker

genes were then generated by thresholding these rankings by the first gene to have a lower ranking, i.e. better fit to, a different meta-pathway.

3.4.15 Methyl-CpG binding domain sequencing (MBD-seq)

For genome-wide DNA methylation analysis, we carried out MBD-seq as described previously (Bock et al., 2010; Harris et al., 2010; Sinclair et al., 2015), but with significant modifications at the SKCCC Experimental and Computational Genomics Core at the Johns Hopkins University. Briefly, 100 ~ 200 ng of genomic DNA was sonicated to an average size of 200 ~ 400 bp and subsequently methylated DNA fragments were enriched using modified MBD polypeptides immobilized on protein A magnetic beads (NEB, EpiMark Methylated DNA Enrichment Kit) according to the manufacturer's protocol. Then, the enriched DNA fragments were eluted and prepared as barcoded next generation sequencing libraries using the ThruPlex DNA library preparation kit (Rubicon Genomics) according to the supplied protocols. The libraries were then sequenced by massively-parallel 50-bp single-end sequencing on an Illumina HiSeq 2500 in rapid run mode. Reads were aligned to the mm10 mouse reference genome using bowtie2 (Langmead and Salzberg, 2012) and duplicated reads were removed. For identifying differential methylated CpG island promoters, the data was normalized using TMM normalization (Trimmed Mean of M-values) (Robinson and Oshlack, 2010). After normalization, the sum of MBD-seq counts for each promoter region with CpG islands and without CpG island was

CHAPTER 3. SINGLE-STEP INDUCTION OF RIGHT-SIDED COLON CANCER
PHENOTYPE BY *BRAF*^{V600E} THROUGH ACQUIRED WNT ACTIVATION

computed. Promoters with CpG islands are defined as any promoter TSS regions within 500bp from an annotated CpG island (downloaded from UCSC). Fisher test comparing the promoter regions in the test data set (*BRAF*^{FCA}, *BRAF*^{FCA-IND} or *KRAS*^{CA}) with that in WT (Bock et al., 2010). Promoters that showed an 8-fold change in read counts and with a Benjamini & Hochberg corrected p-value < 0.05 were identified as significantly differential methylated promoters.

PHENOTYPE BY *BRAF^{V600E}* THROUGH ACQUIRED WNT ACTIVATION

Figure 3.3

Figure 3.3 *BRAF^{V600E}* and to a lesser extent, *KRAS^{G12D}* induce organoids to manifest spheroid formation with inward polypoid growth

(A-B) H&E histology section and phase contrast image of wild-type organoids. The organoids consist of central cystic body of single layer of epithelial cells and outward crypt-like budding structure (wide triangle arrowhead). (C-D) H&E histology section and phase contrast image of *BRAF^{CA}*. The organoids showed inward budding structure (narrow triangle arrowhead) in the central cystic body and dysplastic changes such as high nuclear to cytosol ratio. (E-F) H&E histology section and phase contrast image of *KRAS^{CA}*. The organoids are forming spheroids consisting of single layer of epithelial cells. Occasionally, *KRAS^{CA}* organoids also have inward growth.

CHAPTER 3. SINGLE-STEP INDUCTION OF RIGHT-SIDED COLON CANCER PHENOTYPE BY *BRAF^{V600E}* THROUGH ACQUIRED WNT ACTIVATION

Figure 3.4

Figure 3.4 Only *BRAF*^{V600E} drives acquisition of stem cell niche factor independency

(A) Schematic diagram of niche factor dependency assay. Each organoid clone was grown in five different media conditions, full factor ENSW, partially deficient media NSW, NS and N and fully deficient media Base media for one week and their growth was quantified by CellTiter-Glo assay using half of the organoids in each well. The other half was plated for the subsequent culture and growth quantification for another two weeks. (B) Summary of media conditions. “+” means addition of the factor. “-“ means deficiency of the factor. (C) Heatmap showing relative growth of each organoids in different media conditions in three weeks. Relative growth rates for each condition are calculated in comparison to ENSW media condition. The green color indicates equivalent growth as in ENSW. The red color indicates no growth. Only the three *BRAF*^{CA} replicates grown for 5 months (5M) were able to sustain growth in all media conditions including Base media. The continuing culture (dotted arrow) of the *BRAF*^{CA} replicates in Base media established independent organoids *BRAF*^{CA-IND}1-3. (“-2M” indicates organoids that had been cultured for 2 months after induction. “-5M” indicates organoids that had been cultured for 5 months after induction.)

PHENOTYPE BY *BRAF*^{V600E} THROUGH ACQUIRED WNT ACTIVATION

Figure 3.5

**Figure 3.5 Niche factor independent BRAF^{CA} organoids (BRAF^{CA-IND})
manifest augmented polypoid growth and dysplasia**

(A-B) H&E histology section and phase contrast image of BRAF^{CA-IND}. The organoids manifest inward multilayer growth (double simple arrowhead) and augmented dysplastic features.

CHAPTER 3. SINGLE-STEP INDUCTION OF RIGHT-SIDED COLON CANCER PHENOTYPE BY *BRAF*^{V600E} THROUGH ACQUIRED WNT ACTIVATION

Figure 3.6

CHAPTER 3. SINGLE-STEP INDUCTION OF RIGHT-SIDED COLON CANCER
PHENOTYPE BY $BRAF^{V600E}$ THROUGH ACQUIRED WNT ACTIVATION

Figure 3.6 (continued)

Figure 3.6 The niche factor independency of BRAF^{CA-IND} organoids are not due to increased secretion of niche factors by the organoids

(A) Schematic diagram of co-culture experiment. BRAF^{CA-IND} organoids were mixed with BRAF^{EV} or KRAS^{CA} and the mixed organoids were separated into two wells to grow in ENSW and Base for one week. After one week, the co-cultures were examined by mutant specific PCR and fluorescence microscope. (B) Mutant specific PCR to examine survival of each organoid types in the culture. The rec⁻-BRAF^{V600E} band, the non-rec-BRAF band and the rec⁻-KRAS^{G12D} band indicate the presence of BRAF^{CA-IND}₁₋₂, BRAF^{EV}₁₋₂ and KRAS^{CA}₂, respectively. Only the rec⁻-BRAF^{V600E} originated from BRAF^{CA-IND} was detected in both ENSW and Base media. The non-rec-BRAF from BRAF^{EV} and rec⁻-KRAS^{G12D} from KRAS^{CA} were detected only in full factor ENSW media not in Base media. (C) Fluorescence microscope images of co-cultures of BRAF^{CA-IND} with BRAF^{EV} in ENSW and Base media. BRAF^{CA-IND} organoids are red-fluorescent due to expression of tdTomato and BRAF^{EV} are non-fluorescent. In ENSW media, both fluorescent BRAF^{CA-IND} and non-fluorescent BRAF^{EV} survived. However, in Base media, only fluorescent BRAF^{CA-IND} clones survived. (D) One week culture of BRAF^{EV} organoids in Base media showed complete disintegration of BRAF^{EV} organoids in absence of the niche factors.

CHAPTER 3. SINGLE-STEP INDUCTION OF RIGHT-SIDED COLON CANCER PHENOTYPE BY *BRAF^{V600E}* THROUGH ACQUIRED WNT ACTIVATION

Figure 3.7

Figure 3.7 *BRAF^{CA-IND}* organoids are resistant to Porcupine inhibitor IWP2

(A) Schematic diagram of post-translational processing of Wnt ligands. Wnt proteins are palmitoylated by Porcupine and transported to the cis-Golgi network to be secreted outside. IWP2 inhibits palmitoylation of Wnt by Porcupine and therefore blocks secretion of Wnt. (B) Heatmap showing growth of each organoid in response to IWP-2, a Porcupine inhibitor in NS media. Relative growth rates of organoid at each IWP-2 concentration are calculated in comparison to the growth in DMSO treatment and are displayed as green for no growth inhibition and red for complete growth inhibition. The growth of WT and *BRAF^{EV}* was completely inhibited at as low as 2.5mM dose. However, the growth of *KRAS^{CA}* replicates was not completely inhibited although their growth was compromised. One of *BRAF^{CA}* replicates, *BRAF^{CA1}* was completely resistant to IWP2 and the other two, *BRAF^{CA2-3}* showed partial resistance to IWP2. All three *BRAF^{CA-IND}* replicates showed complete resistance to IWP2.

D

BRAFCA-XT

Figure 3.8 A single step transformation by *BRAF^{V600E}* induces right-sided CRC phenotype

(A) Growth curve of xenograft tumors. None of WT and KRAS^{CA} forms tumors. All the implantations using BRAF^{CA-IND} form tumors. Two replicates of BRAF^{CA} also form tumors as well. (B) Gross morphology of BRAF^{CA-IND} tumor. The tumors (white triangle) were gelatinous with copious amount of mucin. (C) Histology of human mucinous adenocarcinoma from TCGA database (TCGA-AA-3877). The tumor largely consists of mucin (*) filled cysts lined by piled up (barbed arrowhead) dysplastic cells. Occasionally, cells with a large vacuole (signet ring cell) present (simple arrow). (D) Histology of xenograft tumors (BRAF^{CA-XT}). The tumors consist of mucin (*) filled cysts lined by piled up dysplastic epithelial cells (barbed arrowhead) displaying high nuclear to cytoplasm ratio (double simple arrowhead), bizarre looking mitotic figures (narrow triangle arrowhead) and multinucleation (wide triangle arrowhead). Occasionally, signet ring cells (simple arrowhead) are observed.

CHAPTER 3. SINGLE-STEP INDUCTION OF RIGHT-SIDED COLON CANCER
PHENOTYPE BY *BRAF*^{V600E} THROUGH ACQUIRED WNT ACTIVATION

Figure 3.9

Figure 3.9 The transformed *BRAF^{V600E}* organoids are invasive and metastatic

(A) Gross morphology of invading tumor (black triangle) (*BRAF^{FCA-IND1}*). The organoids invaded to the peritoneum and grew as a tumor in the kidney capsule. (B) Gross morphology of metastatic tumor (white arrow) (*BRAF^{FCA-IND1}*). The organoids were digested into single cells and one million cells were injected into tail vein of NSG mice. The cells injected into blood stream survived and formed xenograft tumors. (C) Histology of invading tumors. Tumors implanted in subcutaneous space (white triangle) invaded through peritoneal muscle layer and grew as a tumor in kidney capsule (black triangle). Occasionally, the tumor cells were observed in space between muscle layers (black and white barbed arrowhead) showing evidence of invasiveness.

CHAPTER 3. SINGLE-STEP INDUCTION OF RIGHT-SIDED COLON CANCER
PHENOTYPE BY *BRAF*^{V600E} THROUGH ACQUIRED WNT ACTIVATION

Figure 3.10

Figure 3.10 *BRAF* mutation is highly associated with mucinous adenocarcinoma histopathology type

(A) Contingency table between *BRAF* mutation status and tumor histopathology type (mucinous vs non-mucinous adenocarcinoma) (B) Contingency analysis between *BRAF* mutation status and tumor histopathology type (mucinous vs non-mucinous adenocarcinoma). *BRAF* mutation is highly associated with mucinous CRC.

CHAPTER 3. SINGLE-STEP INDUCTION OF RIGHT-SIDED COLON CANCER PHENOTYPE BY *BRAF*^{V600E} THROUGH ACQUIRED WNT ACTIVATION

Figure 3.11

**Figure 3.11 Only *BRAF^{V600E}* induces Wnt / beta-catenin pathway in
niche factor deficient media**

(A) Schematic diagram of experiment design for gene expression microarray and flow cytometry analysis. WT, *BRAF^{EV}*, *BRAF^{CA}*, *KRAS^{CA}* and *BRAF^{CA-IND}* were plated in two well separately and were grown in ENSW media and BASE media for 48hr. After 48hr, the organoids were harvested for gene expression microarray and flow cytometry. (B) Schematic diagram of GSEA analysis. The gene expression patterns of *BRAF^{CA}*, *BRAF^{CA-IND}* and *KRAS^{CA}* are compared to those of WT and *BRAF^{EV}*. (C) Both *BRAF^{V600E}* and *KRAS^{G12D}* induce Myc targets. However, only *BRAF^{V600E}* but not *KRAS^{G12D}*, induces Wnt / beta-catenin pathway in niche factor deficient media.

CHAPTER 3. SINGLE-STEP INDUCTION OF RIGHT-SIDED COLON CANCER PHENOTYPE BY *BRAF^{V600E}* THROUGH ACQUIRED WNT ACTIVATION

Figure 3.12

Figure 3.12 The CoGAPs pattern analysis discovered four different patterns of gene expression in the different types of organoids

(A) Schematic diagram of experiment design for gene expression microarray and flow cytometry analysis. It is the same as in Figure 3.12. (B) Schematic diagram of CoGAPS analysis. CoGAPS algorithm is used to recognize agnostically patterns of gene expressions of the different organoids in ENSW and Base media. In each pattern, gene set enrichment analysis was done to discover specific pathways involved. (C) Heatmap of gene expression patterns. CoGAPS algorithm discovered four different patterns of gene expression. The pattern 1 genes are those up-regulated in ENSW media and down-regulated in Base media in WT / *BRAF*^{EV}. However, their expression are sustained high in *BRAF*^{CA-IND}. Although their expression are not sustained in *KRAS*^{CA} and *BRAF*^{CA} in Base media as in WT / *BRAF*^{EV}, the extent of down-regulation is less than in WT / *BRAF*^{EV}. The pattern 2 has the opposite direction. The genes in the pattern 2 are down-regulated in ENSW and up-regulated in BASE in WT / *BRAF*^{EV}. However, their expression are sustained low in *BRAF*^{CA-IND}. Their expression in *KRAS*^{CA} and *BRAF*^{CA} are also up-regulated but to a lesser extent than in WT / *BRAF*^{EV}. The pattern 3 and 4 are genes that have genotype specific changes. Pattern 3 genes have high expression in WT / *BRAF*^{EV}. Pattern 4 genes have high expression in *BRAF*^{CA-IND} and low expression in WT / *BRAF*^{EV}.

CHAPTER 3. SINGLE-STEP INDUCTION OF RIGHT-SIDED COLON CANCER
PHENOTYPE BY *BRAF^{V600E}* THROUGH ACQUIRED WNT ACTIVATION

Figure 3.13

Figure 3.13 *BRAF*^{V600E} promotes sustained up-regulation of intestinal stem cell and proliferation genes and intestinal Wnt target genes even upon deprivation of all niche factors

(A) Pattern 1 is enriched for intestinal Wnt target genes and genes that are upregulated in intestinal stem cells and proliferating cells (TA cells). (B) Pattern 2 is enriched with genes upregulated in differentiated epithelial cells (C-D) Pattern 3 and 4 are enriched with differentiation genes.

Figure 3.14

**Figure 3.14 Sustained up-regulation of intestinal stem cell markers,
CD44 and Sox9 in BRAF^{CA-IND} organoids**

(A-B) Quantitative RT-PCR results of CD44 and Sox9. Ct values were normalized to GAPDH and fold changes in Base media culture compared to ENSW media were calculated. Grey color represents for WT / BRAF^{EV}, cadetblue for BRAF^{CA}, aquamarine for BRAF^{CA-IND} and brown for KRAS^{CA}.

CHAPTER 3. SINGLE-STEP INDUCTION OF RIGHT-SIDED COLON CANCER
PHENOTYPE BY *BRAF^{V600E}* THROUGH ACQUIRED WNT ACTIVATION

PHENOTYPE BY *BRAF^{V600E}* THROUGH ACQUIRED WNT ACTIVATION

Figure 3.15 (continued)

B Base media

Figure 3.15 (continued)

Figure 3.15 Sustained up-regulation of intestinal stem cells (CD44+) in *BRAF^{CA-IND}* organoids

(A) Flow cytometry analysis for CD44 positive stem cells in organoids in ENSW and Base media. WT and *BRAF^{EV}* organoids consistently have the lowest number of CD44 positive stem cells in ENSW media. *KRAS^{CA}* and *BRAF^{CA}* have higher number than WT / *BRAF^{EV}* but less than *BRAF^{CA-IND}*. 48 hour deprivation of the niche factors reduces CD44 positive stem cells significantly in WT, *BRAF^{EV}*, *KRAS^{CA}* and *BRAF^{CA}*. However, the CD44 positive stem cells number is increased in all replicates of *BRAF^{CA-IND}*. (C) WT and *BRAF^{EV}* organoids consistently have the lowest number of CD44 positive stem cells in ENSW media. *KRAS^{CA}* and *BRAF^{CA}* have higher number than WT / *BRAF^{EV}* but less than *BRAF^{CA-IND}*. 48 hour deprivation of the niche factors reduces CD44 positive stem cells in WT, *BRAF^{EV}*, *KRAS^{CA}* and *BRAF^{CA}*. Only the reduction in WT / *BRAF^{EV}* is statistically significant. However, the CD44 positive stem cells number is increased in all replicates of *BRAF^{CA-IND}*. *BRAF^{CA-IND}* replicates have higher number of stem cells compared to WT / *BRAF^{EV}* in both full media and deprivation media (Base) with a statistical significance.

Figure 3.16

Figure 3.16 Schematic diagram Methyl CpG binding domain (MBD)

DNA methylation sequencing

(A) Schematic diagram Methyl CpG binding domain (MBD) sequencing. The genomic DNA is sheared first and denatured. Then short single strands of DNA with CpG methylation are pulled down with Methyl CpG binding domain (MBD). The pull-down DNA strands are sequenced and aligned in the genome.

Figure 3. 17

A

B

Figure 3.17 *BRAF*^{V600E} induces more differential DNA methylation than *KRAS*^{G12D} preferentially in Wnt pathway genes

(A) Graph showing differential DNA methylation in *BRAF*^{CA}, *BRAF*^{CA-IND}, *KRAS*^{CA} compared to WT. There is higher number of methylated genes in *BRAF*^{CA-IND} compared to *KRAS*^{CA}. (B) KEGG gene ontology analysis revealed preferential methylation change in melanogenesis and Wnt signaling in *BRAF*^{CA-IND}.

CHAPTER 3. SINGLE-STEP INDUCTION OF RIGHT-SIDED COLON CANCER
PHENOTYPE BY *BRAF^{FV600E}* THROUGH ACQUIRED WNT ACTIVATION

Figure 3.18

Figure 3.18 (Continued)

Figure 3.18 *BRAF^{V600E}* induces differential DNA methylation at the promoter CpG islands of Wnt negative regulators and CIMP marker genes

(A) Representative CpG island promoter regions of Wnt negative regulators. All of regions have an increase of DNA methylation at their promoter CpG island in *BRAF^{CA-IND}* and partially in *BRAF^{CA}* implicating epigenetic silencing of Wnt negative regulators. (B) Representative CpG island promoter regions of CIMP genes. The regions have increased DNA methylation in *BRAF^{CA-IND}* and partially in *BRAF^{CA}*. (C) Representative CpG island promoter regions of differentiation genes. Promoter CpG islands of those genes are methylated in *BRAF^{CA-IND}* and partially in *BRAF^{CA}* implicating suppression of differentiation signaling in the organoids.

Figure 3.19 A single-step induction of right-sided CRC phenotype by *BRAF*^{V600E} through acquired Wnt activation induced by accumulation of DNA methylation

(A) Upon induction of *BRAF*^{V600E}, the organoids accumulate DNA methylation on promoter CpG island of Wnt negative regulators and CIMP genes including cell cycle checkpoint genes. The accumulation of DNA methylation on those regions, in turn, induces niche factor independency through autonomous Wnt activation and sustained stemness. The niche factor independent organoids are fully transformed to form xenograft tumors which recapitulate human right-sided *BRAF* mutant tumors in terms of histopathology and DNA methylation patterns. However, induction of *KRAS*^{G12D} is not sufficient to make these changes and full transformation.

Figure 3.20

A

Figure 3.20 Interaction between organoids and stromal fibroblast can be modeled with the current *BRAF^{V600E}* mutant organoids

(A) Stromal fibroblast are reported to have a intensive interaction with epithelial cells through Hippo, Hedgehog and other signaling. The interaction can be modeled and studied by co-culturing our *BRAF^{V600E}* mutant organoids with intestinal stromal fibroblasts.

Zollner, S.K., Rossig, C., and Toretsky, J.A. (2015). Synovial sarcoma is a gateway to the role of chromatin remodeling in cancer. *Cancer Metastasis Rev* 34, 417-428.

CURRICULUM VITAE

Byunghak Kang

The Johns Hopkins University, School of Medicine
Department of Cancer Biology
Bunting Blaustein Cancer Research Bldg. (CRB1) Suite 541
1650 Orleans Street
Baltimore, MD 21287
Email: dvm.kang@gmail.com / bkang7@jhmi.edu
Tel: 410-955-8506
Mobile: 443-326-7593

EDUCATION

- Aug 2010 - present **The Johns Hopkins University**, School of Medicine, Baltimore, MD
PhD (expected in June 2016) in Pathobiology
- Mar 2003 - Feb 2007 **Seoul National University (SNU)**, College of Veterinary Medicine,
Seoul, South Korea
Doctor of Veterinary Medicine (*summa cum laude*)
- Mar 2001 - Feb 2003 **SNU**, College of Natural Science, Seoul, South Korea
Pre-veterinary medicine course

RESEARCH EXPERIENCE

- Aug 2010 - present **Graduate Student Researcher**
The Johns Hopkins University, School of Medicine, Baltimore, MD
- *Thesis Advisors:* Stephen B. Baylin, MD, and Hariharan Easwaran, PhD
- *Thesis:* Phenotypic and molecular profiling of Colorectal cancer tumorigenesis using colon organoid
- *Thesis committee:*
Dr. Benho Park, Associate Director, Breast and Ovarian Cancer Program
Dr. Srinivasan Yegnashubramanian, Director, Next Generation Sequencing Center
Dr. Nicholas Zachos, Director, Mouse Physiology Core
- Sep 2009 - Jul 2010 **Research Assistant**
Chromatin Dynamics Research Center, College of Natural Sciences, SNU, Seoul, South Korea
- *Advisor:* Sung-hee Baek, PhD
- *Research Project:* Phenotyping of ROR-alpha mutant mouse with a focus on modulation of inflammatory signaling by ROR-alpha
- May 2007 - Aug 2009 **Lecturer in Veterinary Pathology and Project Leader**
College of Veterinary Science, Asunción National University (UNA), Misiones Campus, Misiones, Paraguay
- *Funding:* Korea International Cooperation Agency (KOICA)
- *Research Project:* Epidemiologic study of Brucellosis and Tuberculosis in bovine population in San Juan Bautista using field diagnostic kits

CURRICULUM VITAE

- Jul 2004 - Jan 2006 **Research Intern (during summer and winter breaks, four times in total)**
Veterinary Pathology Laboratory, College of Veterinary Medicine, SNU, Seoul, South Korea
- *Advisor:* Chanhee Chae, DVM, PhD
- *Research project:* A retrospective epidemiological study of swine hepatitis E virus in Korea between 1995 and 2004 (resulted in publication in *Vet. J.*)
- *Efficacy and safety test for a mycoplasma hyopneumoniae vaccine for pigs:* Participated in necropsies and gross and histologic evaluations of lesions
- *Diagnosis service:* Participated in daily necropsies and sign-outs (5-10 per day)

CLINICAL/PATHOLOGY EXPERIENCE

- Aug-Sep 2015 **Translational Rotation at Phenotyping and Pathology Core (Director: Cory Brayton DVM, Diplomate ACLAM, ACVP)**
The Johns Hopkins University, School of Medicine, Baltimore, MD
- Implemented phenotyping projects: necropsy, trimming, data collection, and histological analysis
- Participated in group study sessions: Gross pathology and AFIP study set
- May 2007-Aug 2009 **Attending Veterinarian**
College of Veterinary Science, UNA, Misiones campus, Misiones, Paraguay
- *Funding:* KIOCA
- Provided daily clinical services for mixed animals: Bovine (50%), Small animal (25%), Equine (10%), Ovine (10%), and others (5%)
- Mar 2004-Sep 2006 **Founder and President**
Veterinary Volunteer Club, "Pallas," College of Veterinary Medicine, SNU, Seoul, South Korea
- *Advisor:* Hwayoung Yoon, DVM, PhD
- Organized regular clinical services for animal shelters every 2-3 months
- Planned and led two-week summer volunteering trip to Sri Lanka
- Provided Rabies vaccine and spay/neutering to stray dogs and cats
- Feb 2006 **Winter Break Externship**
Hyunlee Large Animal Clinic, Kyunggi-do, South Korea
- Participated in daily clinical services for dairy and beef cows
- Jul 2002-Feb 2003 **Extern (during summer and winter breaks)**
New York Animal Clinic, Seoul, South Korea
- Assisted clinical services for small animals

CURRICULUM VITAE

TEACHING & MENTORING EXPERIENCE

- Jul 2014-
Mar 2016 **Supervisor** of laboratory students
The Johns Hopkins University, School of Medicine, Baltimore, MD
- Mentoring high school student (teaching basic laboratory skills and molecular biology techniques, including subcloning)
- Supervised first-year rotation graduate student through his rotation project (taught experimental techniques, such as 3D culture of crypt stem cells)
- 2014 &
2011 **Teaching Assistant** for graduate-level course, *Pathology for Graduate Students: Basic Mechanisms of Disease*
The Johns Hopkins University, School of Medicine, Baltimore, MD
- Developed and graded homework and examinations in 2011, prepared and gave lecture on anatomy and physiology of male reproductive organs in 2014
- May 2007-
Aug 2009 **Lecturer in Veterinary Pathology**
College of Veterinary Science, UNA, Misiones campus, Misiones, Paraguay
- Co-taught veterinary pathology courses to second-year veterinary students: gave lectures and supervised necropsies and diagnostic tests
- Initiated and led outreach program for rural area of Paraguay with veterinary students during summer breaks (provided clinical services for mixed animals including vaccinations, deworming, diagnostic tests, and surgeries)

EXTRACURRICULAR ACTIVITIES

- Sep 2011-
Aug 2012 **Manager of General Affairs**
Baltimore Life Scientist Association, Baltimore, MD
- Organized annual conference and monthly seminars
- Mar 2004 -
Feb 2005 **Board Member of National Council of Veterinary Students**
- Attended monthly meetings of the council and discussed issues related to veterinary education and career development
- Mar 2004 -
Feb 2005 **Vice President of Student Association of College of Veterinary Medicine**
College of Veterinary Medicine, SNU, Seoul, South Korea
- Organized quarterly board meetings and planned college's activities including spring and fall festivals and summer camps
- Led consulting project for veterinary curriculum reform (proposal was later accepted and implemented by College of Veterinary Medicine)

CURRICULUM VITAE

AWARDS AND FELLOWSHIPS

| | |
|------------------------|---|
| 2016 | Graduate Student Association travel award |
| 2016 | Outstanding Abstract/Poster Award Pathology Young Investigator Award |
| 2015 | Best Poster Presentation Award Johns Hopkins Pathobiology Program Annual Retreat |
| 2015 | GI Core Grant for Pilot Studies (US\$25,000) Developed research strategies for the proposal |
| 2015 | 1st Place Winner , Johns Hopkins Biotech and Healthcare Case Competition |
| 2013 | Mokam Fellowship (US\$10,000), academic merit-based fellowship |
| 2012 | Best Poster Presentation Award Baltimore Life Scientist Association Annual Conference |
| Sep 2010 - Aug 2011 | Margaret Lee Fellowship Financial support for tuition and stipends |
| 2007 | Dean's Award at Graduation, SNU Given to one student from each college based on academic achievements and extracurricular activities |
| Mar 2003 - Feb 2007 | Full Tuition Academic Scholarship by College of Veterinary Medicine, SNU Given to student ranked number one in the class Partial Tuition Academic Scholarship by College of Veterinary Medicine, SNU Given to students in top 10% of class |
| Mar 2001 - Feb 2003 | Partial Tuition Academic Scholarship by College of Natural Science, SNU Given to students in top 10% of class |
| 1999 | Seoul High School Student Award Given to students with outstanding academic potential in Seoul |

CURRICULUM VITAE

PROFESSIONAL QUALIFICATIONS AND CERTIFICATIONS

- 2015 **Partial Completion of ECFVG(Educational Commission for Foreign Veterinary Graduate)**
Step 1: Registration and Proof of Graduation (*completed*)
Step 2: English Language Ability (*completed*)
Step 3: Basic and Clinical Science Examination (*completed*)
Step 4: Clinical Proficiency Examination (*completed 6 out of 7 sections*)
- 2012 **Completion of Mouse Pathobiology and Phenotyping Short Course**
Johns Hopkins University School of Medicine, Baltimore, MD, USA
- 2007 **Official Development Aid Training Certificate by KOICA**
- 2007 **Veterinary License in South Korea**

PUBLICATIONS

- **Kang B**, Maegawa S In J, Zachos NC, Huso DL, Issa JP Easwaran H, Baylin SB (*in preparation*). Oncogenic BRAF mutation V600E drives stem cell niche factors-independent growth and tumorigenic transformation in colon organoids.
- Sysa-Shah P, Tocchetti CG, Gupta M, Rainer PP, Shen X, **Kang B**, Belmonte F, Li J, Xu Y, Guo X, Bedja D, Gao WD, Paolocci N, Rath R, Sawyer DB, Naga Prasad SV, Gabrielson K(2016) Bidirectional cross-regulation between ErbB2 and β -adrenergic signaling pathways. *Cardiovasc Res.* 1;109(3):358-73.
- Le A, Stine ZE, Nguyen C, Afzal J, Sun P, Hamaker M, Siegel NM, Gouw AM, **Kang BH**, Yu SH, Cochran RL, Sailor KA, Song H, Dang CV (2014). Tumorigenicity of hypoxic respiring cancer cells revealed by a hypoxia-cell cycle dual reporter. *Proc Natl Acad Sci USA.* 111(34):12486-91.
- Sysa-Shah P, Xu Y, Guo X, Belmonte F, **Kang B**, Bedja D, Pin S, Tsuchiya N, Gabrielson K (2012). Cardiac-specific over-expression of epidermal growth factor receptor2 (ErbB2) induces pro-survival pathways and hypertrophic cardiomyopathy in mice. *PLoS One.* 7(8):e42805.
- Jung K, **Kang B**, Song DS, Chae C (2007). Prevalence and genotyping of hepatitis E virus in swine population in Korea between 1995 and 2004: A retrospective study. *Vet. J.* 173(3):683-687.

CURRICULUM VITAE

ABSTRACT & PRESENTATIONS

- 2016** Kang B, Easwaran H, Baylin S. Oncogenic BRAF mutation V600E drives stem cell niche factors-independent growth and tumorigenic transformation in colon organoids. Abstract/Poster presentation at American Association of Cancer Research Annual meeting, New Orleans LA.
- 2015** Kang B, Easwaran H, Baylin S. Oncogenic BRAF mutation V600E drives stem cell niche factors-independent growth and tumorigenic transformation in colon organoids. Abstract/Poster presentation at Johns Hopkins Pathobiology Program Annual Retreat, Baltimore MD.
- 2012** Kang B, Gabrielson K. Cross-talk between ErbB2 and β -adrenergic signaling pathways. Abstract/Poster presentation at Baltimore Life Scientist Association Annual Conference, Baltimore MD.

PROFESSIONAL MEMBERSHIPS

- ACVP (American College of Veterinary Pathology)
- STP (Society of Toxicologic Pathology)
- AVMA (American Veterinary Medical Association)
- KVMA (Korean Veterinary Medical Association)
- KSEA (Korean-American Scientists and Engineers Association)
- BLSA (Baltimore Life Scientist Association)
- KOV (Korean Overseas Volunteers)
